## Foreword

To understand hydrochemistry and to analyze natural as well as man-made impacts on aquatic systems, hydrogeochemical models have been used since the 1960's and more frequently in recent times.

Numerical groundwater flow, transport, and geochemical models are important tools besides classical deterministic and analytical approaches. Solving complex linear or non-linear systems of equations, commonly with hundreds of unknown parameters, is a routine task for a PC.

Modeling hydrogeochemical processes requires a detailed and accurate water analysis, as well as thermodynamic and kinetic data as input. Thermodynamic data, such as complex formation constants and solubility-products, are often provided as databases within the respective programs. However, the description of surface-controlled reactions (sorption, cation exchange, surface complexation) and kinetically controlled reactions requires additional input data.

Unlike groundwater flow and transport models, thermodynamic models, in principal, do not need any calibration. However, considering surface-controlled or kinetically controlled reaction models might be subject to calibration.

Typical problems for the application of geochemical models are:

- speciation
- determination of saturation indices
- adjustment of equilibria/disequilibria for minerals or gases
- mixing of different waters
- modeling the effects of temperature
- stoichiometric reactions (e.g. titration)
- reactions with solids, fluids, and gaseous phases (in open and closed systems)
- sorption (cation exchange, surface complexation)
- inverse modeling
- kinetically controlled reactions
- reactive transport

Hydrogeochemical models depend on the quality of the chemical analysis, the boundary conditions presumed by the program, theoretical concepts (e.g. calculation of activity coefficients) and the thermodynamic data. Therefore it is vital to check the results critically. For that, a basic knowledge about chemical and thermodynamic processes is required and will be outlined briefly in the following chapters on hydrogeochemical equilibrium (chapter 1.1), kinetics (chapter 1.2), and transport (chapter 1.3). Chapter 2 gives an overview on standard

hydrogeochemical programs, problems and possible sources of error for modeling, and a detailed introduction to run the program PHREEQC, which is used in this book. With the help of examples, practical modeling applications are addressed and specialized theoretical knowledge is extended. Chapter 4 presents the results for the exercises of chapter 3. This book does not aim to replace a textbook but rather attempts to be a practical guide for beginners at modeling.

# Table of Contents

<b>1 Theoretical Background.....</b>	<b>1</b>
1.1 Equilibrium reactions.....	1
1.1.1 Introduction.....	1
1.1.2 Thermodynamic fundamentals.....	5
1.1.2.1 Mass-action law .....	5
1.1.2.2 Gibbs free energy .....	7
1.1.2.3 Gibbs phase rule.....	8
1.1.2.4 Activity.....	8
1.1.2.5 Ionic strength.....	10
1.1.2.6 Calculation of activity coefficient .....	10
1.1.2.6.1. Theory of ion-association .....	10
1.1.2.6.2. Theory of ion-interaction.....	13
1.1.2.7 Comparison ion-association versus ion-interaction theory.....	14
1.1.3 Interactions at the liquid-gaseous phase boundary.....	17
1.1.3.1 Henry Law.....	17
1.1.4 Interactions at the liquid-solid phase boundary.....	19
1.1.4.1 Dissolution and precipitation.....	19
1.1.4.1.1. Solubility-product.....	19
1.1.4.1.2. Saturation index.....	22
1.1.4.1.3. Limiting mineral phases .....	22
1.1.4.2 Sorption.....	25
1.1.4.2.1. Hydrophobic/hydrophilic substances .....	25
1.1.4.2.2. Ion exchange.....	25
1.1.4.2.3. Mathematical description of the sorption .....	30
1.1.5 Interactions in the liquid phase .....	35
1.1.5.1 Complexation .....	35
1.1.5.2 Redox processes.....	37
1.1.5.2.1. Measurement of the redox potential .....	37
1.1.5.2.2. Calculation of the redox potential .....	38
1.1.5.2.3. Presentation in predominance diagrams .....	43
1.1.5.2.4. Redox buffer.....	47
1.1.5.2.5. Significance of redox reactions .....	47
1.2 Kinetics.....	50
1.2.1 Kinetics of various chemical processes.....	50
1.2.1.1 Half-life .....	50
1.2.1.2 Kinetics of mineral dissolution.....	51
1.2.2 Calculation of the reaction rate .....	52
1.2.2.1 Subsequent reactions .....	53

1.2.2.2 Parallel reactions .....	54
1.2.3 Controlling factors on the reaction rate .....	54
1.2.4 Empirical approaches for kinetically controlled reactions .....	55
1.3 Reactive mass transport .....	58
1.3.1 Introduction .....	58
1.3.2 Flow models .....	58
1.3.3 Transport models .....	59
1.3.3.1 Definition .....	59
1.3.3.2 Idealized transport conditions .....	61
1.3.3.3 Real transport conditions .....	61
1.3.3.3.1. Exchange within double-porosity aquifers .....	62
1.3.3.4 Numerical methods of transport modeling .....	63
1.3.3.4.1. Finite-difference/finite-element method .....	65
1.3.3.4.2. Coupled methods .....	66
<b>2 Hydrogeochemical Modeling Programs .....</b>	<b>69</b>
2.1 General .....	69
2.1.1 Geochemical algorithms .....	69
2.1.2 Programs based on minimizing free energy .....	71
2.1.3 Programs based on equilibrium constants .....	72
2.1.3.1 PHREEQC .....	72
2.1.3.2 EQ 3/6 .....	74
2.1.4 Thermodynamic databases .....	76
2.1.4.1 General .....	76
2.1.4.2 Structure of thermodynamic databases .....	78
2.1.5 Problems and sources of error in geochemical modeling .....	81
2.2 Use of PHREEQC .....	85
2.2.1 The structure of PHREEQC and its graphical user interfaces .....	85
2.2.1.1 Input .....	88
2.2.1.2 Database .....	95
2.2.1.3 Output .....	96
2.2.1.4 Grid .....	97
2.2.1.5 Chart .....	97
2.2.2 Introductory Examples for PHREEQC Modeling .....	97
2.2.2.1 Equilibrium reactions .....	97
2.2.2.1.1. Example 1a standard output – seawater analysis .....	98
2.2.2.1.2. Example 1b equilibrium – solution of gypsum .....	100
2.2.2.1.3. Example 1c equilibrium – solution of calcite with CO <sub>2</sub> .....	101
2.2.2.1.4. Example 1d: Modeling uncertainties – LJUNGSKILE .....	103
2.2.2.2 Introductory example for sorption .....	107
2.2.2.3 Introductory examples for kinetics .....	114
2.2.2.3.1. Defining reaction rates .....	115
2.2.2.3.2. BASIC within PHREEQC .....	117
2.2.2.4 Introductory example for isotope fractionation .....	122
2.2.2.5 Introductory examples for reactive mass transport .....	126

2.2.2.5.1. Simple 1D transport: column experiment.....	126
2.2.2.5.2. 1D transport, dilution, and surface complexation in an abandoned uranium mine .....	130
2.2.2.5.3. 3D transport with PHAST .....	134
<b>3 Exercises .....</b>	<b>141</b>
3.1 Equilibrium reactions.....	143
3.1.1 Groundwater – Lithosphere .....	143
3.1.1.1 Standard output well analysis.....	143
3.1.1.2 Equilibrium reaction – solubility of gypsum.....	144
3.1.1.3 Disequilibrium reaction – solubility of gypsum.....	144
3.1.1.4 Temperature dependency of gypsum solubility in well water...144	
3.1.1.5 Temperature dependency of gypsum solubility in pure water...144	
3.1.1.6 Temperature- and P(CO <sub>2</sub> )-dependent calcite solubility.....	144
3.1.1.7 Calcite precipitation and dolomite dissolution .....	145
3.1.1.8 Calcite solubility in an open and a closed system .....	145
3.1.1.9 Pyrite weathering .....	145
3.1.2 Atmosphere – Groundwater – Lithosphere .....	146
3.1.2.1 Precipitation under the influence of soil CO <sub>2</sub> .....	146
3.1.2.2 Buffering systems in the soil.....	147
3.1.2.3 Mineral precipitates at hot sulfur springs .....	147
3.1.2.4 Formation of stalactites in karst caves.....	148
3.1.2.5 Evaporation .....	149
3.1.3 Groundwater .....	150
3.1.3.1 The pE-pH diagram for the system iron .....	150
3.1.3.2 The Fe pE-pH diagram considering carbon and sulfur.....	152
3.1.3.3 The pH dependency of uranium species.....	152
3.1.4 Origin of groundwater.....	153
3.1.4.1 Pumping of fossil groundwater in arid regions .....	155
3.1.4.2 Salt water/fresh water interface.....	156
3.1.5 Anthropogenic use of groundwater.....	157
3.1.5.1 Sampling: Ca titration with EDTA.....	157
3.1.5.2 Carbonic acid aggressiveness.....	157
3.1.5.3 Water treatment by aeration – well water.....	158
3.1.5.4 Water treatment by aeration – sulfur spring.....	158
3.1.5.5 Mixing of waters .....	159
3.1.6 Rehabilitation of groundwater.....	159
3.1.6.1 Reduction of nitrate with methanol .....	159
3.1.6.2 Fe(0) barriers.....	160
3.1.6.3 Increase in pH through a calcite barrier .....	160
3.2 Reaction kinetics.....	160
3.2.1 Pyrite weathering .....	160
3.2.2 Quartz-feldspar-dissolution.....	161
3.2.3 Degradation of organic matter within the aquifer on reduction of redox-sensitive elements (Fe, As, U, Cu, Mn, S).....	162

3.2.4 Degradation of tritium in the unsaturated zone .....	163
3.3 Reactive transport .....	166
3.3.1 Lysimeter .....	166
3.3.2 Karst spring discharge.....	167
3.3.3 Karstification (corrosion along a karst fracture) .....	168
3.3.4 The pH increase of an acid mine water.....	169
3.3.5 In-situ leaching.....	170
3.3.6 3D Transport – Uranium and arsenic contamination plume .....	171
<b>4 Solutions.....</b>	<b>173</b>
4.1 Equilibrium reactions.....	173
4.1.1 Groundwater – Lithosphere .....	173
4.1.1.1 Standard output well analysis.....	173
4.1.1.2 Equilibrium reaction – solubility of gypsum.....	175
4.1.1.3 Disequilibrium reaction – solubility of gypsum .....	175
4.1.1.4 Temperature dependency of gypsum solubility in well water....	176
4.1.1.5 Temperature dependency of gypsum solubility in pure water....	177
4.1.1.6 Temperature- and $P(\text{CO}_2)$ -dependent calcite solubility.....	177
4.1.1.7 Calcite precipitation and dolomite dissolution .....	178
4.1.1.8 Comparison of the calcite solubility in an open and a closed system .....	179
4.1.1.9 Pyrite weathering .....	179
4.1.2 Atmosphere – Groundwater – Lithosphere .....	181
4.1.2.1 Precipitation under the influence of soil $\text{CO}_2$ .....	181
4.1.2.2 Buffering systems in the soil.....	181
4.1.2.3 Mineral precipitations at hot sulfur springs.....	182
4.1.2.4 Formation of stalactites in karst caves.....	183
4.1.2.5 Evaporation .....	183
4.1.3 Groundwater .....	184
4.1.3.1 The pE-pH diagram for the system iron .....	184
4.1.3.2 The Fe pE-pH diagram considering carbon and sulfur.....	186
4.1.3.3 The pH dependency of uranium species.....	187
4.1.4 Origin of groundwater.....	188
4.1.4.1 Pumping of fossil groundwater in arid regions .....	188
4.1.4.2 Salt water/fresh water interface.....	189
4.1.5 Anthropogenic use of groundwater.....	190
4.1.5.1 Sampling: Ca titration with EDTA.....	190
4.1.5.2 Carbonic acid aggressiveness.....	191
4.1.5.3 Water treatment by aeration – well water.....	191
4.1.5.4 Water treatment by aeration – sulfur spring.....	191
4.1.5.5 Mixing of waters .....	193
4.1.6 Rehabilitation of groundwater.....	194
4.1.6.1 Reduction of nitrate with methanol .....	194
4.1.6.2 Fe(0) barriers.....	195
4.1.6.3 Increase in pH through a calcite barrier .....	196

# 1 Theoretical Background

## 1.1 Equilibrium reactions

### 1.1.1 Introduction

Chemical reactions determine occurrence, distribution, and behavior of aquatic species. Aquatic species are defined as organic and inorganic substances dissolved in water in contrast to colloids (1-1000 nm) and particles (> 1000 nm). This definition includes free anions and cations sensu strictu as well as complexes (chapter 1.1.5.1). The term complex applies to negatively charged species such as  $\text{OH}^-$ ,  $\text{HCO}_3^-$ ,  $\text{CO}_3^{2-}$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{PO}_4^{3-}$ , positively charged species such as  $\text{ZnOH}^+$ ,  $\text{CaH}_2\text{PO}_4^+$ ,  $\text{CaCl}^+$ , and zero-charged species such as  $\text{CaCO}_3^0$ ,  $\text{FeSO}_4^0$  or  $\text{NaHCO}_3^0$  as well as organic ligands. Table 1 shows a selection of inorganic elements and examples of their dissolved species including both generally predominant and less common species.

**Table 1** Selected inorganic elements and examples of aquatic species

Elements	
Major elements (>5 mg/L)	
Calcium (Ca)	$\text{Ca}^{2+}$ , $\text{CaOH}^+$ , $\text{CaF}^+$ , $\text{CaCl}_2^0$ , $\text{CaCl}^+$ , $\text{CaSO}_4^0$ , $\text{CaHSO}_4^+$ , $\text{CaNO}_3^+$ , $\text{CaPO}_4^+$ , $\text{CaHPO}_4^0$ , $\text{CaH}_2\text{PO}_4^+$ , $\text{CaP}_2\text{O}_7^{2-}$ , $\text{CaCO}_3^0$ , $\text{CaHCO}_3^+$ , $\text{Ca}_2(\text{UO}_2)(\text{CO}_3)_3^0$ , $\text{CaB}(\text{OH})_4^+$
Magnesium (Mg)	$\text{Mg}^{2+}$ , $\text{MgOH}^+$ , $\text{MgF}^+$ , $\text{MgSO}_4^0$ , $\text{MgHSO}_4^+$ , $\text{MgCO}_3^0$ , $\text{MgHCO}_3^+$
Sodium (Na)	$\text{Na}^+$ , $\text{NaF}^0$ , $\text{NaSO}_4^-$ , $\text{NaHPO}_4^-$ , $\text{NaCO}_3^-$ , $\text{NaHCO}_3^0$ , $\text{NaCrO}_4^-$
Potassium (K)	$\text{K}^+$ , $\text{KSO}_4^-$ , $\text{KHPO}_4^-$ , $\text{KCrO}_4^-$
Carbon (C)	$\text{HCO}_3^-$ , $\text{CO}_3^{2-}$ , $\text{CO}_2(\text{g})$ , $\text{CO}_2(\text{aq})$ , $\text{Ag}(\text{CO}_3)_2^{2-}$ , $\text{AgCO}_3^-$ , $\text{BaCO}_3^0$ , $\text{BaHCO}_3^+$ , $\text{CaCO}_3^0$ , $\text{CaHCO}_3^+$ , $\text{Ca}_2(\text{UO}_2)(\text{CO}_3)_3^0$ , $\text{Cd}(\text{CO}_3)_3^{4-}$ , $\text{CdHCO}_3^+$ , $\text{CdCO}_3^0$ , $\text{CuHCO}_3^+$ , $\text{CuCO}_3^0$ , $\text{Cu}(\text{CO}_3)_2^{2-}$ , $\text{MgCO}_3^0$ , $\text{MgHCO}_3^+$ , $\text{MnHCO}_3^+$ , $\text{NaCO}_3^-$ , $\text{NaHCO}_3^0$ , $\text{Pb}(\text{CO}_3)_2^{2-}$ , $\text{PbCO}_3^0$ , $\text{PbHCO}_3^+$ , $\text{RaCO}_3^0$ , $\text{RaHCO}_3^+$ , $\text{SrCO}_3^0$ , $\text{SrHCO}_3^+$ , $\text{UO}_2\text{CO}_3^0$ , $\text{UO}_2(\text{CO}_3)_2^{2-}$ , $\text{UO}_2(\text{CO}_3)_3^{4-}$ , $\text{Ca}_2(\text{UO}_2)(\text{CO}_3)_3^0$ , $\text{ZnHCO}_3^+$ , $\text{ZnCO}_3^0$ , $\text{Zn}(\text{CO}_3)_2^{2-}$
Sulfur (S)	$\text{SO}_4^{2-}$ , $\text{SO}_3^{2-}$ , $\text{S}_2\text{O}_3^{2-}$ , $\text{S}_x^-$ , $\text{H}_2\text{S}(\text{g/aq})$ , $\text{HS}^-$ , $\text{Al}(\text{SO}_4)_2^-$ , $\text{AlSO}_4^+$ , $\text{BaSO}_4^0$ , $\text{CaSO}_4^0$ , $\text{CaHSO}_4^+$ , $\text{Cd}(\text{SO}_4)_2^{2-}$ , $\text{CdSO}_4^0$ , $\text{CoSO}_4^0$ , $\text{CoS}_2\text{O}_3^0$ , $\text{CrO}_3\text{SO}_4^{2-}$ , $\text{CrOHSO}_4^0$ , $\text{CrSO}_4^+$ , $\text{Cr}_2(\text{OH})_2(\text{SO}_4)_2^0$ , $\text{CuSO}_4^0$ , $\text{Fe}(\text{SO}_4)_2^-$ , $\text{FeSO}_4^0$ , $\text{FeSO}_4^+$ , $\text{HgSO}_4^0$ , $\text{LiSO}_4^-$ , $\text{MgSO}_4^0$ , $\text{MgHSO}_4^+$ , $\text{MnSO}_4^0$ , $\text{NaSO}_4^-$ , $\text{NiSO}_4^0$ , $\text{Pb}(\text{SO}_4)_2^{2-}$ , $\text{PbSO}_4^0$ , $\text{RaSO}_4^0$ , $\text{SrSO}_4^0$ , $\text{Th}(\text{SO}_4)_4^{4-}$ , $\text{Th}(\text{SO}_4)_3^{2-}$ , $\text{Th}(\text{SO}_4)_2^0$ , $\text{ThSO}_4^{2+}$ , $\text{U}(\text{SO}_4)_2^0$ , $\text{USO}_4^{2+}$ , $\text{UO}_2\text{SO}_4^0$ , $\text{AsO}_3\text{S}^{3-}$ , $\text{AsO}_2\text{S}_2^{3-}$ , $\text{AsOS}_3^{3-}$ , $\text{AsS}_4^{3-}$ , $\text{Cd}(\text{HS})_4^2$ , $\text{Cd}(\text{HS})_3^-$ , $\text{Cd}(\text{HS})_2^0$ , $\text{CdHS}^+$ , $\text{Co}(\text{HS})_2^0$ , $\text{CoHS}^+$ , $\text{Cu}(\text{S}_4)_2^{3-}$ , $\text{Cu}(\text{HS})_3^-$ , $\text{Fe}(\text{HS})_3^-$ , $\text{Fe}(\text{HS})_2^0$ , $\text{HgS}_2^{2-}$ , $\text{Hg}(\text{HS})_2^0$

	$\text{MoO}_2\text{S}_2^{2-}$ , $\text{MoOS}_3^{2-}$ , $\text{Pb(HS)}_3^-$ , $\text{Pb(HS)}_2^0$ , $\text{Sb}_2\text{S}_4^{2-}$
Chlorine (Cl)	$\text{Cl}^-$ , $\text{ClO}^-$ , $\text{ClO}_2^-$ , $\text{ClO}_3^-$ , $\text{ClO}_4^-$ , $\text{AgCl}_4^{3-}$ , $\text{AgCl}_3^{2-}$ , $\text{AgCl}_2^-$ , $\text{AgCl}^0$ , $\text{BaCl}^+$ , $\text{CaCl}_2^0$ , $\text{CaCl}^+$ , $\text{CdCl}_3^-$ , $\text{CdCl}_2^0$ , $\text{CdOHCl}^0$ , $\text{CdCl}^+$ , $\text{CoCl}^+$ , $\text{CrO}_3\text{Cl}^-$ , $\text{CrOHCl}_2^0$ , $\text{CrCl}_2^{2+}$ , $\text{CrCl}^{2+}$ , $\text{CuCl}_3^{2-}$ , $\text{CuCl}_4^{2-}$ , $\text{CuCl}_3^-$ , $\text{CuCl}_2^-$ , $\text{CuCl}_2^0$ , $\text{CuCl}^+$ , $\text{FeCl}_3^0$ , $\text{FeCl}_2^+$ , $\text{FeCl}^{2+}$ , $\text{HgCl}_4^{2-}$ , $\text{HgCl}_3^-$ , $\text{HgCl}_2^0$ , $\text{HgCl}^0$ , $\text{HgClOH}^0$ , $\text{HgCl}^+$ , $\text{LiCl}^0$ , $\text{MnCl}_3^-$ , $\text{MnCl}_2^0$ , $\text{MnCl}^+$ , $\text{NiCl}^+$ , $\text{PbCl}_4^{2-}$ , $\text{PbCl}_3^-$ , $\text{PbCl}_2^0$ , $\text{PbCl}^+$ , $\text{RaCl}^+$ , $\text{ThCl}_4^0$ , $\text{ThCl}_3^+$ , $\text{ThCl}_2^+$ , $\text{ThCl}^{3+}$ , $\text{TlCl}_2^-$ , $\text{TlCl}_4^-$ , $\text{TlCl}^0$ , $\text{TlCl}_3^0$ , $\text{TlCl}_2^+$ , $\text{TlOHCl}^+$ , $\text{TlBrCl}^-$ , $\text{TlCl}^{2+}$ , $\text{UO}_2\text{Cl}^+$ , $\text{UCl}^{3+}$ , $\text{ZnCl}_4^{2-}$ , $\text{ZnCl}_3^-$ , $\text{ZnCl}_2^0$ , $\text{ZnOHCl}^0$ , $\text{ZnCl}^+$
Nitrogen (N)	$\text{NO}_3^-$ , $\text{AgNO}_3^0$ , $\text{BaNO}_3^-$ , $\text{CrNO}_3^{2+}$ , $\text{CoNO}_3^+$ , $\text{Hg(NO}_3)_2^0$ , $\text{HgNO}_3^+$ , $\text{Mn(NO}_3)_2^0$ , $\text{Ni(NO}_3)_2^0$ , $\text{NiNO}_3^+$ , $\text{TiNO}_3^{2+}$ , $\text{NO}_2^-$ , $\text{NO}_{(g/aq)}^0$ , $\text{NO}_{2(g/aq)}^0$ , $\text{N}_2\text{O}_{(g/aq)}^0$ , $\text{NH}_3(g/aq)$ , $\text{HNO}_2(g/aq)$ , $\text{NH}_4^+$ , $\text{Cr(NH}_3)_4(\text{OH})_2^-$ , $\text{Cr(NH}_3)_5\text{OH}^{2+}$ , $\text{Cr(NH}_3)_6\text{Br}^{2+}$ , $\text{Cr(NH}_3)_6^{3+}$ , $\text{HgNH}_3^{2+}$ , $\text{Hg(NH}_3)_2^{2+}$ , $\text{Hg(NH}_3)_3^{2+}$ , $\text{Hg(NH}_3)_4^{2+}$ , $\text{Ni(NH}_3)_2^{2+}$ , $\text{Ni(NH}_3)_6^{2+}$
Silicon (Si)	$\text{H}_4\text{SiO}_4^0$ , $\text{H}_3\text{SiO}_4^-$ , $\text{H}_2\text{SiO}_4^{2-}$ , $\text{SiF}_6^{2-}$ , $\text{UO}_2\text{H}_3\text{SiO}_4^+$
Minor elements (0.1-5 mg/L)	
Boron (B)	$\text{B(OH)}_3^0$ , $\text{BF}_2(\text{OH})^-$ , $\text{BF}_3\text{OH}^-$ , $\text{BF}_4^-$ , $\text{CaB(OH)}_4^+$

Besides inorganic species, numerous organic (Table 2) and organisms (Table 3) are encountered in water that are of great importance for water quality.

**Table 2** Selected organic substances (plus-sign in brackets means that geogenic formation in traces is possible, only the typical concentration range is indicated)

Substance	geogenic	anthropogenic	typical range of concentration
Humic matter	+	-	mg/L
aliphatic carbons: oil, fuel	+	+	mg/L
Phenols	+	+	mg/L
BTEX (benzene, toluene, ethylbenzene, xylene)	(+)	+	µg/L
PAHs (polycyclic aromatic hydrocarbons)	(+)	+	µg/L
PCBs (polychlorinated biphenyls)	-	+	µg/L
CFC's (Chlorofluorocarbons)	-	+	ng/L
Dioxins, furans	(+)	+	pg/L
pesticides	(+)	+	ng/L
hormones	(+)	+	pg/L
pharmaceuticals	-	+	pg/L

**Table 3** Organisms in groundwater

	size
Virus	5 - 300 nm
Prokaryotes: Bacteria & Archaea (methanogenous, extreme halophiles, extreme thermophiles)	100 - 15.000 nm
Eukaryotes: Protozoa (Foraminifera, Radiolaria, Dinoflagellata) Yeast (anaerob) Fungi (aerob)	> 3 µm ~20 µm
Fish (Brotulidae, Amblyopsidae, Astyanax Jordani, Caecobarbus Geertsi) in Karst aquifers	mm... cm dm... m

Interactions of different species within the aqueous phase (chapter 1.1.5), with gases (chapter 1.1.3), and solid phases (minerals) (chapter 1.1.4.) as well as

transport (chapter 1.3) and decay processes (biological decomposition, radioactive decay) are fundamental in determining the hydrogeochemical composition of ground and surface water.

Hydrogeochemical reactions involving only a single phase are called homogeneous, whereas heterogeneous reactions occur between two or more phases such as gas and water, water and solids, or gas and solids. In contrast to open systems, closed systems enable only exchange of energy, not constituents with the surrounding environment.

Chemical reactions can be described by thermodynamics (chapter 1.1.2) and kinetics (chapter 1.2). Reactions expressed by the mass-action law (chapter 1.1.2.1), are thermodynamically reversible and independent of time. In contrast, kinetic processes are time-dependent reactions. Models that take into account kinetics can describe irreversible reactions such as decay processes that require finite amounts of time.

## 1.1.2 Thermodynamic fundamentals

### 1.1.2.1 Mass-action law

In principle, any chemical equilibrium can be described by the mass-action law.

$$K = \frac{\{C\}^c \cdot \{D\}^d}{\{A\}^a \cdot \{B\}^b} \quad \text{Eq. (2.)}$$

With a, b, c, d = number of moles of the reactants A, B, and the end products C, D, respectively for the given reaction, (1);

K = thermodynamic equilibrium or dissociation constant (general term)

In particular, the term K is defined in relation to the following types of reactions:

- Dissolution/precipitation (chapter 1.1.4.1)  
K<sub>s</sub> = solubility-product
- Sorption (chapter 1.1.4.2)  
K<sub>d</sub> = distribution coefficient  
K<sub>x</sub> = selectivity coefficient
- Complex formation/dissolution of complexes (chapter 1.1.5.1)  
K = complexation constant, stability constant
- Redox reaction (chapter 1.1.5.2)  
K = stability constant

If one reverses reactants and products in a reaction equation, the solubility constant K' equals 1/K. Hence, it is important when reporting an equilibrium constant to always refer to the corresponding reaction equation. Furthermore, one must distinguish between conditional constants, which are valid only for certain conditions of temperature and ionic strength, and generally applicable constants, at

standard state conditions (i.e.  $T=25^{\circ}\text{C}$  and ionic strength  $I=0$ , infinitely diluted solution). The latter might be calculated from the former. Standard temperature conditions can be calculated using the van't Hoff equation (Eq. 3):

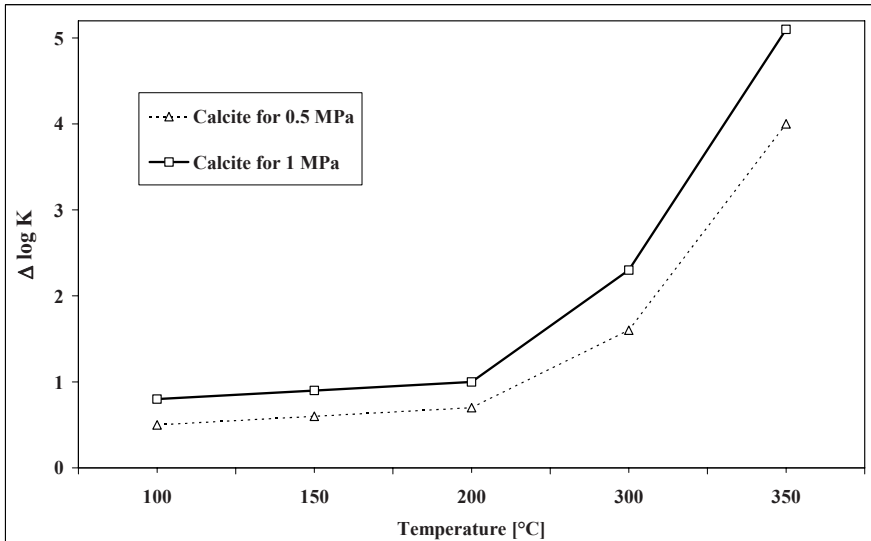

$$\log(K_r) = \log(K_0) + \frac{H_r^0}{2.303 \cdot R} \cdot \frac{T_K - T_{K0}}{T_K \cdot T_{K0}} \quad \text{Eq. (3.)}$$

- with
- $K_r$  = equilibrium constant at measured temperature
  - $K_0$  = equilibrium constant at standard temperature
  - $T_K$  = measured temperature in degrees Kelvin
  - $T_{K0}$  = temperature in Kelvin, at which the standard enthalpy  $H_r^0$  was determined
  - $R$  = ideal gas constant (8.315 J/K mol)

Transformation to standard pressure is done using the following equation (Eq. 4):

$$\ln K(P) = \ln K(S) - \frac{\Delta V(T)}{T \cdot R \cdot \beta} \cdot \ln \frac{\sigma(P)}{\sigma(S)} \quad \text{Eq. (4.)}$$

- with
- $K(P)$  = equilibrium constant at pressure  $P$
  - $K(S)$  = equilibrium constant at saturated vapor pressure
  - $\Delta V(T)$  = volume change of the dissociation reaction at temperature  $T$  and saturated vapor pressure  $S$
  - $\beta$  = isothermal compressibility coefficient of water at  $T$  and  $P$
  - $\sigma(P)$  = density of water at pressure  $P$
  - $\sigma(S)$  = density of water at saturated vapor pressure

**Fig. 1 Influence of pressure and temperature on the solubility of calcite (after Kharaka et al. 1988)**

Fig. 1 shows calcite dissolution dependent on different pressure and temperature conditions.

If a process consists of a series of subsequent reactions, as for instance the dissociation of  $\text{H}_2\text{CO}_3$  to  $\text{HCO}_3^-$  and to  $\text{CO}_3^{2-}$ , stability (dissociation) constants are numbered consecutively (e.g.  $K_1$  and  $K_2$ ).

### 1.1.2.2 Gibbs free energy

A system at constant temperature and pressure is in disequilibrium until all of its Gibbs free energy,  $G$ , is consumed. At equilibrium, Gibbs free energy is zero.

The Gibbs free energy is a measure of the probability that a reaction occurs. It is defined by the enthalpy,  $H$ , and the entropy,  $S^0$  (Eq. 5). The enthalpy can be described as the thermodynamic potential, which ensues  $H = U + p \cdot V$ , where  $U$  is the internal energy,  $p$  is the pressure, and  $V$  is the volume. The entropy, according to classical definitions, is a measure of molecular order of a thermodynamic system and the irreversibility of a process, respectively.

$$G = H - S^0 \cdot T \quad \text{Eq. (5.)}$$

with  $T$  = temperature in Kelvin

A positive value for  $G$  means that additional energy is required for the reaction to happen, and a negative value means that the reaction occurs spontaneously, thereby releasing energy.

The change in free energy of a reaction is directly related to the change in energy of the activities of all reactants and products under standard conditions.

$$G = G^0 + R \cdot T \cdot \ln \frac{\{C\}^c \cdot \{D\}^d}{\{A\}^a \cdot \{B\}^b} \quad \text{Eq. (6.)}$$

with  $R$  = ideal gas constant

$G^0$  = standard Gibbs free energy at 25°C and 100 kPa

$G^0$  equals  $G$ , when all reactants have the same activity. Then, the term within the logarithm in Eq. 6 is 1 and the logarithm becomes zero.

The equation can further be simplified in equilibrium, when  $G$  equals zero, to:

$$G^0 = -R \cdot T \cdot \ln K \quad \text{Eq. (7.)}$$

Accordingly  $G$  enables a prediction on the equilibrium of the reaction  $aA + bB \leftrightarrow cC + dD$ . With  $G < 0$ , reactants will be consumed while the concentration of products increases, for  $G > 0$  product are consumed and reactants formed.

### 1.1.2.3 Gibbs phase rule

The Gibbs phase rule gives the number of degrees of freedom that result from the number of components and phases, coexisting in a system.

$$F = C - P + 2 \quad \text{Eq. (8.)}$$

with  $F$  = number of degrees of freedom  
 $C$  = number of components  
 $P$  = number of phases

The number 2 in the Eq. 8 arises from the two independent variables, pressure and temperature. Phases are limited, physically and chemically homogeneous, mechanically separable parts of a system. Components are defined as simple chemical entities or units that comprise the composition of a phase.

In a system, where the number of phases and the number of components are equal, there are two degrees of freedom, i.e. that two variables can be varied independently (e.g. temperature and pressure). If the number of the degrees of freedom is zero, temperature and pressure are constant and the system is invariant.

In a three-phase system including a solid and a liquid as well as a gas, the Gibbs phase rule is modified to:

$$F = C' - N - P + 2 \quad \text{Eq. (9.)}$$

with  $F$  = number of the degrees of freedom  
 $C'$  = number of different chemical species  
 $N$  = number of possible equilibrium reactions (species, charge balance, stoichiometric relations)  
 $P$  = number of phases

### 1.1.2.4 Activity

Using the mass-action law, quantities of substances are represented as activities,  $a_i$ , and not as concentrations,  $c_i$ , with respect to a species,  $i$ .

$$a_i = f_i \cdot c_i \quad \text{Eq.(10.)}$$

In Eq. 10, the activity coefficient,  $f_i$ , is an ion-specific correction factor that describes interactions among charged ions. Since the activity coefficient is a non-linear function of ionic strength, the activity is a non-linear function of the concentration, too.

The activity decreases with increasing ionic strength up to 0.1 mol/kg and is always lower than the concentration, because charged ions reduce each other's activities in solution through interactions. Thus, the activity coefficient is less than 1 (Fig. 2). It is obvious from Fig. 2 that when increasing the ion concentrations the decrease in activity is the more significant the higher the valence of the ions. In the ideal case of an infinitely dilute solution, where ion-interactions are close to zero, the activity coefficient is 1 and the activity equals the concentration.

Fig. 2 Relation between ionic strength and activity coefficient in a range up to 0.1 mol/L (after Hem 1985)

Experimentally, only mean activity coefficients can be determined for salts, not activity coefficients for single ions. According to the MacInnes Convention, however, it can be assumed that cations and anions formed upon dissolution of one compound have the same activity coefficients because of their same charge, similar size, electron configuration and mobility, e.g.:

$$f_i(K^+) = f_i(Cl^-) = f_{\pm}(KCl) \quad \text{Eq.(11.)}$$

### 1.1.2.5 Ionic strength

The ionic strength, as a sum parameter for ionic interactions, is calculated as one-half the sum of the products of each species in moles,  $m_i$ , and their respective charge  $z_i$ .

$$I = 0.5 \cdot \sum m_i \cdot z_i^2 \quad \text{Eq.(12.)}$$

### 1.1.2.6 Calculation of activity coefficient

#### 1.1.2.6.1. Theory of ion-association

When the ionic strength of a solution is known, e.g. from a chemical analysis, the activity coefficient can be calculated using several approximation equations. All of them are basically inferred from the DEBYE-HÜCKEL limiting-law equation and differ in the range of the ionic strength they can be applied for.

DEBYE-HÜCKEL limiting-law equation (Debye & Hückel 1923)

$$\log(f_i) = -A \cdot z_i^2 \cdot \sqrt{I} \quad I < 0.005 \text{ mol/kg} \quad \text{Eq.(13.)}$$

extended DEBYE-HÜCKEL limiting-law equation

$$\log(f_i) = \frac{-A \cdot z_i^2 \cdot \sqrt{I}}{1 + B \cdot a_i \cdot \sqrt{I}} \quad I < 0.1 \text{ mol/kg} \quad \text{Eq.(14.)}$$

GÜNTEMBERG equation (Güntelberg 1926)

$$\log(f_i) = -0.5 z_i^2 \frac{\sqrt{I}}{1 + 1.4 \sqrt{I}} \quad I < 0.1 \text{ mol/kg} \quad \text{Eq.(15.)}$$

DAVIES equation (Davies 1962, 1938)

$$\log(f_i) = -A \cdot z_i^2 \left( \frac{\sqrt{I}}{1 + \sqrt{I}} - 0.3 \cdot I \right) \quad I < 0.5 \text{ mol/kg} \quad \text{Eq.(16.)}$$

“WATEQ” DEBYE-HÜCKEL equation (Hückel 1925)

$$\log(f_i) = \frac{-A \cdot z_i^2 \cdot \sqrt{I}}{1 + B \cdot a_i \cdot \sqrt{I}} + b_i \cdot I \quad I < 1 \text{ mol/kg} \quad \text{Eq.(17.)}$$

with  $f$  = activity coefficient  
 $z$  = valence  
 $I$  = ionic strength

$a_i, b_i$  = ion-specific parameters (dependent on the ion radius) (selected values see Table 4, complete overview in van Gaans (1989) and Kharaka et al. (1988))

A, B temperature-dependent parameters, calculated from the following empirical equations (Eq. 18 to Eq. 21)

$$A = \frac{1.82483 \cdot 10^6 \cdot \sqrt{d}}{(\varepsilon \cdot T_K)^{3/2}} \quad \text{Eq.(18.)}$$

$$B = \frac{50.2916 \cdot \sqrt{d}}{(\varepsilon \cdot T_K)^{1/2}} \quad \text{Eq.(19.)}$$

$$d = 1 - \frac{(T_C - 3.9863)^2 \cdot (T_C + 288.9414)}{508929.2 \cdot (T_C + 68.12963)} + 0.011445 \cdot e^{-374.3/T_C} \quad \text{Eq.(20.)}$$

$$\varepsilon = 2727.586 + 0.6224107 \cdot T_K - 466.9151 \cdot \ln(T_K) - \frac{52000.87}{T_K} \quad \text{Eq.(21.)}$$

with  $d$  = density (after Gildseth et al. 1972 for 0-100°)

$\varepsilon$  = dielectric constant (after Nordstrom et al. 1990 for 0-100°C)

$T_C$  = temperature in °Celsius

$T_K$  = temperature in Kelvin

For temperatures of about 25°C and water with a density of 1 g/cm<sup>3</sup>, A is 0.51 and B is 0.33. In some textbooks, B is charted as 0.33·10<sup>8</sup>. For the use of the latter,  $a_i$  must be in cm, otherwise in Å (=10<sup>-8</sup> cm).

**Table 4 Ion-specific parameters  $a_i$  and  $b_i$  (after Parkhurst et al. 1980 and (\*) Truesdell a. Jones 1974)**

SO <sub>4</sub> <sup>2-</sup>	5.31	-0.07

The theory of ion association, using only ionic strength-dependent activity coefficients, is valid to about 1 molal. Above that concentration, it has not been tested. Some authors even believe the upper limit should be at 0.7 mol/kg (which equals sea water). Fig. 3 shows that already at an ionic strength of  $> 0.3$  mol/kg ( $\text{H}^+$ ) the activity coefficient does not decrease any further but starts to increase, and eventually attains values of more than 1. The second term in the DAVIES and extended DEBYE-HÜCKEL limiting-law equations forces the activity coefficient to increase at high ionic strength. This is owed to the fact, that ion-interactions are not only based on Coulomb forces any more, ion sizes change with the ionic strength, and ions with the same charge interact. Moreover, with the increase in the ionic strength, a larger fraction of water molecules is bound to ion hydration sleeves decreasing the concentration of free water molecules and correspondingly increasing the activity relative to 1 kg of free water molecules.

Fig. 3 Relation of ionic strength and activity coefficient in higher concentrated solutions, (up to  $I = 10$  mol/kg), valid ranges for the different electrolyte theories are indicated as lines (modified after Garrels and Christ 1965)

### 1.1.2.6.2. Theory of ion-interaction

For higher ionic strengths, e.g. highly saline waters, the PITZER equation can be used (Pitzer 1973). This semi-empirical model is based also on the DEBYE-HÜCKEL limiting-law equation, but additionally integrates “virial” equations (vires = Latin for forces), that describe ion-interactions (intermolecular forces). Compared to the ion-association theory, parameters for PITZER equation are often lacking for more complex species. Furthermore, a set of equilibrium constants (albeit minimal) for complexation reactions is still required.

In the following a simple version of PITZER equations is briefly described. For complete calculations and description of specific parameters and equations the reader is referred to the original literature (Pitzer 1973, Pitzer 1981, Whitfield 1975, Whitfield 1979, Silvester and Pitzer 1978, Harvie and Weare 1980, Gueddari et al. 1983, Pitzer 1991).

The calculation of the activity coefficient is done separately for positively (index i) and negatively (index j) charged species applying Eq. 22. In the following example the calculation of the activity coefficients is shown for cations; the calculation for anions works correspondingly.

$$\ln f_M = z_M^2 \cdot F + S1 + S2 + S3 + |z_M| \cdot S4 \quad \text{Eq.(22.)}$$

with M = cation

$z_M$  = valence state of cation M

F, S1-S4 = sums, calculated using Eqs. 23-30

$$S1 = \sum_{j=1}^a m_j (2 \cdot B_{Mj} + z \cdot C_{Mj}) \quad \text{Eq.(23.)}$$

$$S2 = \sum_{i=1}^c m_i (2 \cdot \phi_{Mj} + \sum_{j=1}^a m_j \cdot P_{Mij}) \quad \text{Eq.(24.)}$$

$$S3 = \sum_{j=1}^{a-1} \sum_{k=j+1}^a m_j^2 \cdot P_{Mjk} \quad \text{Eq.(25.)}$$

$$S4 = \sum_{i=1}^c \sum_{j=1}^a m_i \cdot m_j \cdot c_{ij} \quad \text{Eq.(26.)}$$

with B, C,  $\Phi$ , P = species-specific parameters

m = molarities [mol/L]

k = index

c = number of cations

a = number of anions

$$F = -\frac{2.303 \cdot A}{3.0} \left( \frac{\sqrt{I}}{1 + 1.2 \cdot \sqrt{I}} + \frac{2}{1.2} \cdot \ln(1 + 1.2 \cdot \sqrt{I}) \right) + S5 + S6 + S7 \quad \text{Eq.(27.)}$$

$$S5 = \sum_{i=1}^c \sum_{j=1}^a m_i \cdot m_j \cdot B'_{ij} \quad \text{Eq.(28.)}$$

$$S6 = \sum_{i=1}^{c-1} \sum_{k=i+1}^c m_i^2 \cdot \phi'_{ik} \quad \text{Eq.(29.)}$$

$$S7 = \sum_{j=1}^{a-1} \sum_{l=j+1}^a m_j^2 \cdot \phi'_{jl} \quad \text{Eq.(30.)}$$

with     A = DEBYE-HÜCKEL constant (Eq. 18)  
           B',  $\Phi'$  = Virial coefficients, modified with regard to the ionic strength  
           k, l = indices

#### 1.1.2.7 Comparison ion-association versus ion-interaction theory

Fig. 4 to Fig. 8 show the substantial differences in activity coefficients for calcium, chloride, sulfate, sodium, and hydrogen calculated based on different ion-association and interaction theories. Activity coefficients were calculated according to Eq. 13 to Eq. 17 for the corresponding ion-association theories. With the program PHRQPITZ activity coefficients were calculated based on the PITZER ion-interaction model. The substantial differences clearly show the limited validity of the different theories.

In particular, the strongly diverging graph of the simple DEBYE-HÜCKEL limiting-law equation from the PITZER curve in the range exceeding 0.005 mol/kg (validity limit) is obvious. In contrast, the conformity of WATEQ-DEBYE-HÜCKEL and PITZER concerning the divalent calcium and sulfate ions is surprisingly good. Also for chloride the WATEQ-DEBYE-HÜCKEL and PITZER equation show a good agreement up to  $I = 3$  mol/kg. On contrary, the activity coefficients for sodium and hydrogen ions show substantial discrepancies. There, the validity range of 1 mol/kg for the WATEQ-DEBYE-HÜCKEL limiting-law equation must be restricted, since significant differences already occur at ionic strengths as low as 0.1 mol/kg (one order of magnitude below the cited limit) in comparison to the PITZER equation. These examples demonstrate the flaws of the ion-association theory, which are especially severe for the mono-valent ions.

Fig. 4 Comparison of the activity coefficient of  $\text{Ca}^{2+}$  in relation to the ionic strength as calculated using a  $\text{CaCl}_2$  solution ( $a_{\text{Ca}} = 4.86$ ,  $b_{\text{Ca}} = 0.15$  Table 4) and different theories of ion-association and the Pitzer equation, dashed lines signify calculated coefficients outside the validity range of the corresponding ion-association theory.

Fig. 5 Comparison of the activity coefficient of  $\text{Cl}^-$  in relation to the ionic strength as calculated using a  $\text{CaCl}_2$  solution ( $a_{\text{Cl}} = 3.71$ ,  $b_{\text{Cl}} = 0.01$  Table 4) and different theories of ion-association and the Pitzer equation, dashed lines signify calculated coefficients outside the validity range of the corresponding ion-association theory.

Fig. 6 Comparison of the activity coefficient of  $\text{SO}_4^{2-}$  in relation to the ionic strength as calculated using a  $\text{Na}_2(\text{SO}_4)$  solution ( $a_{\text{SO}_4^{2-}} = 5.31$ ,  $b_{\text{SO}_4^{2-}} = -0.07$  Table 4) and different theories of ion-association and the PITZER equation, dashed lines signify calculated coefficients outside the validity range of the corresponding ion-association theory.

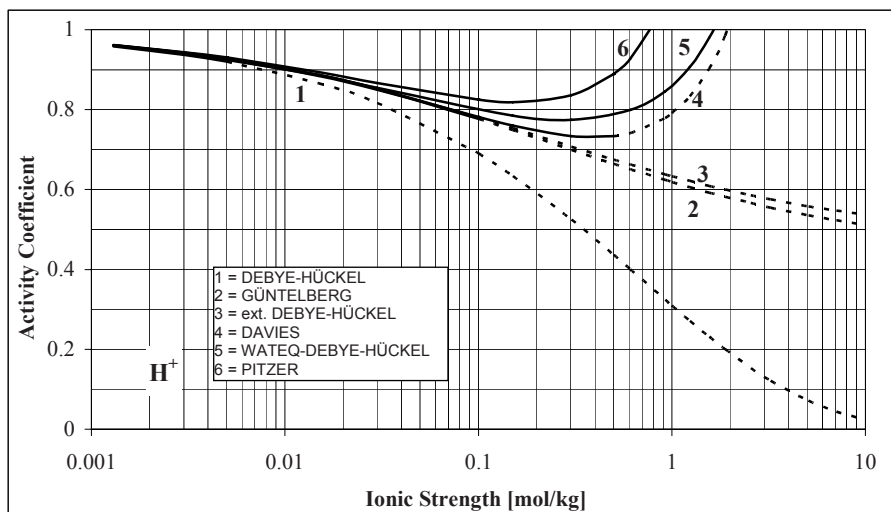

Fig. 7 Comparison of the activity coefficient of  $\text{Na}^+$  in relation to the ionic strength as calculated using a  $\text{Na}_2(\text{SO}_4)$  solution ( $a_{\text{Na}} = 4.32$ ,  $b_{\text{Na}} = 0.06$  Table 4) and different theories of ion-association and the PITZER equation, dashed lines signify calculated coefficients outside the validity range of the corresponding ion-association theory.

**Fig. 8** Comparison of the activity coefficient of  $H^+$  in relation to the ionic strength as calculated from the changing pH of a  $CaCl_2$  solution ( $a_H = 4.78$ ,  $b_H = 0.24$  Table 4) using different theories of ion-association and the PITZER equation, dashed lines signify calculated coefficients outside the validity range of the corresponding ion-association theory.

### 1.1.3 Interactions at the liquid-gaseous phase boundary

#### 1.1.3.1 Henry Law

Using the linear Henry's law, the amount of gas dissolved in water can be calculated for a known temperature and partial pressure.

$$a_i = K_{Hi} \cdot p_i \quad \text{Eq.(31.)}$$

$a_i$  = fugacity (activity) of the gas [mol/kg]

$K_{Hi}$  = Henry constant of the gas  $i$

$p_i$  = partial pressure of the gas  $i$  [kPa]

Table 5 shows the Henry constants and the inferred amount of gas dissolved in water for different gases of the atmosphere. The partial pressures of  $N_2$  and  $O_2$  in the atmosphere at  $25^\circ C$  and  $10^5 Pa$  (1 bar), for example, are 78 kPa and 21 kPa, respectively. These pressures correspond to concentrations of 14.00 mg/L for  $N_2$  and 8.43 mg/L for  $O_2$ .

Gas solubility generally decreases with increasing temperature. For oxygen and nitrogen, e.g. solubility at  $100^\circ C$  is only 45 and 54%, respectively, of that at  $10^\circ C$ . However, in particular for light gases like H and He this inverse correlation does

not hold true. Minimum fugacity for helium e.g. is observed at about 30°C. Both towards lower and higher temperatures fugacity increases (Fig. 9).

**Table 5** Composition of the terrestrial atmosphere, Henry constants and calculated concentrations for equilibrium in water at 25°C, partial pressures of the atmosphere and ionic strength of 0 (according to Alloway and Ayres 1996, Sigg and Stumm 1994, Umweltbundesamt 1988/89).

Gas	volume %	Henry constant $K_H$ (25°C) in mol/ kg·kPa	Concentration in equilibrium	
N <sub>2</sub>	78.1	$6.40 \cdot 10^{-6}$	0.50 mmol/L	14.0 mg/L
O <sub>2</sub>	20.9	$1.26 \cdot 10^{-5}$	0.26 mmol/L	8.43 mg/L
Ar	0.943	$1.37 \cdot 10^{-5}$	12.9 mmol/L	0.515 mg/L
CO <sub>2</sub>	0.028 ... 0.037	$3.39 \cdot 10^{-4}$	consecutive reactions	consecutive reactions
Ne	0.0018	$4.49 \cdot 10^{-6}$	8 nmol/L	0.16 mg/L
He	$0.51 \cdot 10^{-3}$	$3.76 \cdot 10^{-6}$	19 nmol/L	76 ng/L
CH <sub>4</sub>	$1.7 \cdot 10^{-6}$	$1.29 \cdot 10^{-5}$	2.19 nmol/L	35 ng/L
N <sub>2</sub> O	$0.304 \cdot 10^{-6}$	$2.57 \cdot 10^{-4}$	0.078 nmol/L	3.4 ng/L
NO	---	$1.9 \cdot 10^{-5}$	consecutive reactions	consecutive reactions
NO <sub>2</sub>	10 .... $22 \cdot 10^{-9}$	$1.0 \cdot 10^{-4}$	consecutive reactions	consecutive reactions
NH <sub>3</sub>	$0.2 \cdot 2 \cdot 10^{-9}$	0.57	consecutive reactions	consecutive reactions
SO <sub>2</sub>	$10 \cdot 10^{-9}$ ... $19 \cdot 10^{-9}$	0.0125	consecutive reactions	consecutive reactions
O <sub>3</sub>	$10 \cdot 10^{-9}$ ... $100 \cdot 10^{-9}$	$9.4 \cdot 10^{-5}$	0.094 ... 0.94 nmol/L	4.5 ... 45 ng/L

**Fig. 9** Fugacity of different gases with increasing temperature. While the fugacity of oxygen and nitrogen decreases with increasing temperature, helium shows a minimum fugacity at 30°C, increasing both towards lower and higher temperatures (modeled with PHREEQC, based on the LLNL database)

Thus, Henry's law is only directly applicable for gases, which do not undergo spontaneous further reactions, as for example nitrogen, oxygen, or argon. For gases that react with water, Henry's law can only be applied if subsequent reactions are taken into account. One such example where solubility is much higher than calculated by Henry's Law is carbon dioxide. Even though, dependent on pH, only about 1% of  $\text{CO}_2$  spontaneously dissolve in water to form  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$ , subsequent complexation reactions of  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$  with mono- or divalent metals strongly increase the aqueous solubility of  $\text{CO}_2$ . Consumption of protons during mineral dissolution (e.g. calcite) further increases dissolution of  $\text{CO}_2$ .

### **1.1.4 Interactions at the liquid-solid phase boundary**

#### **1.1.4.1 Dissolution and precipitation**

Dissolution and precipitation can be described by the mass-action law as reversible, heterogeneous reactions. In general, the solubility of a mineral is defined as the mass of a mineral, which can be dissolved within a standard volume of the solvent.

##### **1.1.4.1.1. Solubility-product**

The dissolution of a mineral AB into the components A and B occurs according to the mass-action law as follows:

$$K_{\text{sp}} = \frac{\{\text{A}\} \cdot \{\text{B}\}}{\{\text{AB}\}} \quad \text{Eq.(33.)}$$

Since the activity of the solid phase AB is assumed to be constant at 1, the equilibrium constant of the mass-action law results in the following solubility-product constant ( $K_{\text{sp}}$ ) or ion-activity product (IAP):

$$K_{\text{sp}} = \text{IAP} = \{\text{A}\} \cdot \{\text{B}\} \quad \text{Eq.(34.)}$$

It is important to note that analytically determined concentrations for A and B must be transformed into activities and that only the activities of the free ions are considered, not those of the complexes.

The solubility-product depends on the mineral, the solvent, the pressure or the partial pressure of certain gases, the temperature, pH,  $E_{\text{H}}$ , and on the ions previously dissolved in the water and to what extent these have already formed complexes. While partial pressure, pH,  $E_{\text{H}}$ , and complex stability are considered in

the mass-action law, temperature and pressure have to be taken into account by additional factors.

#### Dependency of $K_{SP}$ on the pressure

Up to a pressure equivalent to 500 m water depth (5 MPa) total pressure changes have almost no influence on the solubility-product. There is, however, a strong dependency on the partial pressure of particular gases.

#### Dependency of $K_{SP}$ on the partial pressure

An increased carbon dioxide partial pressure is the main reason for the observed increased rate of dissolution and precipitation in the upper layer of soils. In the growth season the carbon dioxide partial pressure can be about 10 to 100 times higher than in the atmosphere because of the biological and microbiological activity. While the average carbon dioxide partial pressure under humid climate conditions in summer is at 3 to 5 kPa (3-5 vol%), it amounts to up to 30 vol% in tropical climates and to up to 60 vol% in heaps or organically contaminated areas. Since the increased partial pressure of  $CO_2$  is accompanied by a higher proton activity, minerals with increased solubility under acidic conditions are preferably dissolved.

#### Dependency of $K_{SP}$ on the temperature

In contrast to the partial pressure, temperature rise does not generally contribute to an increase in solubility. According to the principle of the smallest constraint (Le Chatelier), only endothermic dissolutions, i.e. reactions, which need additional heat input, are favored (e.g. dissolution of silicates, aluminosilicates, oxides, etc.). The dissolutions of carbonates and sulfates which are exothermic reactions decrease with increasing temperature.

#### Dependency of $K_{SP}$ on the pH value

Few ions are equally soluble over the whole range of pH conditions in natural groundwaters. Especially the dissolution of metals is strongly pH-dependent. While precipitating as hydroxides, oxides, and salts under basic conditions, they dissolve under acid conditions and are highly mobile as free cations. Aluminum is soluble under acid as well as under basic conditions. It precipitates as hydroxide or clay mineral in the pH range of 5 to 8.

#### Dependency of $K_{SP}$ on the $E_H$ value

For redox-sensitive elements, i.e., elements that occur in different oxidation states depending on the prevailing oxidizing or reducing conditions, the solubility does not only depend on the pH only but also on the redox chemistry. For example, uranium in its reduced form as U(4) is almost insoluble at moderate pH values, while U(6) is readily dissolved. For iron (at  $pH > 3$ ) it is vice versa: Substantial amounts can only be dissolved in its reduced form as Fe(2), while Fe(3) rapidly precipitates as ironhydroxides even at low concentrations in solution.

### Dependency of $K_{sp}$ on complex stability

In general, the formation of complexes increases the solubility, while the dissociation of complexes decreases it.

The extent to which elements are soluble and thus more mobile is indicated in Table 6. There, the relative enrichment of the elements in sea water compared to river water is depicted in a periodic system. Substances, which are readily soluble and thus highly mobile are enriched in seawater, whereas less mobile and less soluble substances are depleted.

#### 1.1.4.1.2. Saturation index

The logarithm of the quotient of the ion-activity product (IAP) and solubility-product ( $K_{sp}$ ) is called the saturation index (SI). The IAP is the product of element activities. Analytically determined concentrations have to be transformed to activities considering ionic strength, temperature, and complex formation. The solubility-product is the maximum possible solubility (based on equilibrium solubility data taken from the literature) at the respective water temperature.

$$SI = \log \frac{IAP}{K_{sp}} \quad \text{Eq.(35.)}$$

The saturation index SI indicates, if a solution is in equilibrium, under-saturated or super-saturated with regard to a solid phase. A value of 1 signifies a ten-fold supersaturation, a value of -2 a hundred-fold undersaturation in relation to a certain mineral phase. In practice, equilibrium can be assumed for a range of -0.05 to 0.05. If the determined SI value is below -0.05 the solution is undersaturated with regard to the corresponding mineral, if SI exceeds +0.05 the water is supersaturated with respect to this mineral. Note that supersaturation is not automatically equivalent to precipitation. If precipitation kinetics are slow solutions can remain supersaturated with regard to mineral phases for very long times.

#### 1.1.4.1.3. Limiting mineral phases

Some elements in aquatic systems exist only at low concentrations ( $\mu\text{g/L}$  range) in spite of readily soluble minerals. This phenomenon is not always caused by a generally low occurrence of the respective element in the earth crust mineral as for instance with uranium. Possible limiting factors are the formation of new minerals, co-precipitation, incongruent solutions, and the formation of solid-solution minerals (i.e. mixed minerals).

Formation of new minerals

For example  $\text{Ca}^{2+}$ , in the presence of  $\text{SO}_4^{2-}$  or  $\text{CO}_3^{2-}$  can be precipitated as gypsum or calcite, respectively. A limiting mineral phase for  $\text{Ba}^{2+}$  in the presence of sulfate is  $\text{BaSO}_4$  (barite). If, for instance, a sulfate-containing groundwater is mixed with a  $\text{BaCl}_2$ -containing groundwater, barite becomes the limiting phase and is precipitated until the saturation index for barite attains the value of zero.

Co-precipitation

For elements like radium, arsenic, beryllium, thallium, molybdenum, and many others, not only the low solubility of the related minerals but also the co-precipitation or adsorption with other minerals, plays an important role. For instance radium is co-precipitated with iron hydroxides or barium sulfate. In the case of iron co-precipitation, radium mobility is also determined by the redox chemistry, since iron is a redox-sensitive ion, which only forms iron oxyhydroxides under oxidizing conditions. Thus, radium, even though it forms only divalent species, mimicks the behavior of a redox-sensitive element.

Incongruent solutions

Solution processes, in which one mineral dissolves, while another mineral inevitably precipitates, are called incongruent. When e.g. adding dolomite to water in equilibrium with calcite ( $\text{SI} = 0$ ), dolomite dissolves until equilibrium for dolomite is established. That leads consequently to an increase of Ca, Mg, and C concentrations in water, which in turn inevitably causes super-saturation with respect to calcite and thus precipitation of calcite.

Solid solutions

The examination of naturally occurring minerals shows that pure mineral phases are rare. In particular they frequently contain trace elements as well as common elements. Classic examples of solid-solution minerals are dolomite or the calcite/rhodocrosite, calcite/strontianite, and calcite/otavite systems.

For these carbonates, the calculation of the saturation index gets more difficult. If, for instance, one considers the calcite/strontianite system, the solubility of both mineral phases is estimated by:

$$K_{\text{calcite}} = \frac{\{\text{Ca}^{2+}\} \cdot \{\text{CO}_3^{2-}\}}{\{\text{CaCO}_3\}_s} \quad \text{Eq.(36.)}$$

and

$$K_{\text{strontianite}} = \frac{\{\text{Sr}^{2+}\} \cdot \{\text{CO}_3^{2-}\}}{\{\text{SrCO}_3\}_s} \quad \text{Eq.(37.)}$$

Assuming a solid-solution mineral made up from a mixture of these two minerals, the conversion of the equations results in:

$$\frac{\{Sr^{2+}\}}{\{Ca^{2+}\}} = \frac{K_{\text{strontianite}} \cdot \{SrCO_3\}_s}{K_{\text{calcite}} \cdot \{CaCO_3\}_s} \quad \text{Eq.(38.)}$$

That means that a certain activity ratio of Sr and Ca in aqueous solution is associated with a certain activity ratio in the minerals. Introducing, analogously to the non-ideal behavior of the activity coefficient of the aquatic species, a specific correction factor  $f_{\text{calcite}}$  and  $f_{\text{strontianite}}$  for the activity, leads to the following equation:

$$\frac{K_{\text{strontianite}} \cdot f_{\text{strontianite}}}{K_{\text{calcite}} \cdot f_{\text{calcite}}} = \frac{\{Sr\} \cdot X_{\text{calcite}}}{\{Ca\} \cdot X_{\text{strontianite}}} \quad \text{Eq.(39.)}$$

where X is the molar proportion in the solid-solution mineral. In the simplest case, the ratio of both activity coefficients can be combined in order to obtain a distribution coefficient. The latter can be experimentally determined by semi-empirical approximation in the laboratory.

Using the solubility-product constants for calcite and strontianite and assuming a calcium activity of 1.6 mmol/L, a distribution coefficient of 0.8 for strontium and 0.98 for calcite, and a ratio of 50:1 (=0.02) in the solid-solution mineral, the following equation gives the activity of strontium:

$$\begin{aligned} \{Sr\} &= \frac{K_{\text{strontianite}} \cdot f_{\text{strontianite}} \cdot X_{\text{strontianite}} \cdot \{Ca\}}{K_{\text{calcite}} \cdot f_{\text{calcite}} \cdot X_{\text{calcite}}} \\ &= \frac{10^{-9.271} \cdot 0.8 \cdot 0.02 \cdot 1.6 \cdot 10^{-3}}{10^{-8.48} \cdot 0.98} = 4.2 \cdot 10^{-6} \text{ mol/l} \end{aligned} \quad \text{Eq.(40.)}$$

If strontianite is assumed to be the limiting phase, significantly more strontium (activity approx.  $2.4 \cdot 10^{-4}$  mol/L) could be dissolved compared to that of the solid-solution mineral phase.

This example shows a tendency with solid-solution minerals. There is a supersaturation or an equilibrium regarding the solid-solution minerals but an undersaturation with respect to the pure mineral phases, i.e. the solid-solution mineral is formed but none of the pure mineral phases. The importance of this process depends upon the values of the activity coefficient of the solid-solution component.

For the calculation of solid-solution mineral behavior, two conceptual models may be used: the end-member model (any mixing of two or more phases) and the site-mixing model (substituting elements can replace certain elements only at certain sites within the crystal structure).

For some elements, limiting phases (pure minerals and solid-solution minerals) are irrelevant. Thus, there are no limiting mineral phases for Na or B under natural groundwater conditions. Sorption on organic matter (humic and fulvic acids), on clay minerals or iron oxyhydroxides as well as cation exchange may be limiting factors instead of mineral formation. This issue will be addressed in the following.

### 1.1.4.2 Sorption

The term sorption combines matrix sorption and surface sorption. Matrix sorption can be described as the relatively unspecific exchange of constituents contained in water into the porous matrix of a rock (“absorption”). Surface sorption is understood to be the accretion of atoms or molecules of solutes, gases or vapor at a phase boundary (“adsorption”). In the following only surface sorption will be addressed more thoroughly.

Surface sorption may occur by physical binding forces (van de Waals forces, physisorption), by chemical bonding (Coulomb forces) or by hydrogen bonding (chemisorption). A complete saturation of all free bonds at the defined surface sites is possible involving specific lattice sites and/or functional groups (surface complexation, chapter 1.1.4.2.3). While physisorption is reversible in most cases, remobilization of constituents bound by chemisorption is difficult. Ion exchange is based on electrostatic interactions between differently charged molecules.

#### 1.1.4.2.1. Hydrophobic/hydrophilic substances

Rocks may be hydrophobic or hydrophilic and this property is closely related to the extent of sorption. In contrast to hydrophilic materials, hydrophobic substances show no free valences or electrostatic charges at their surfaces. Hence, neither hydrated water molecules nor dissolved species can be bound to the surface and in the extreme case, surface wetting with aqueous solution could be completely suppressed.

#### 1.1.4.2.2. Ion exchange

The ability of solid substances to exchange cations or anions with cation or anions in aqueous solution is called ion-exchange capacity. In natural systems anions are exchanged very rarely, in contrast to cations, which exchange more readily forming a succession of decreasing intensity:  $\text{Ba}^{2+} > \text{Sr}^{2+} > \text{Ca}^{2+} > \text{Mg}^{2+} > \text{Be}^{2+}$  and  $\text{Cs}^+ > \text{K}^+ > \text{Na}^+ > \text{Li}^+$ . Generally, multivalent ions ( $\text{Ca}^{2+}$ ) are more strongly bound than monovalent ions ( $\text{Na}^+$ ), yet the selectivity decreases with increasing ionic strength (Stumm and Morgan, 1996). Large ions like  $\text{Ra}^{2+}$  or  $\text{Cs}^+$  as well as small ions like  $\text{Li}^+$  or  $\text{Be}^{2+}$  are merely exchanged to a lower extent. The  $\text{H}^+$  proton, having a high charge density and small diameter, is an exception and is preferentially absorbed.

Moreover, the strength of the binding depends on the respective sorbent, as Table 7 shows for some metals. The comparison of the relative binding strength is based on the pH, at which 50% of the metals are absorbed ( $\text{pH}_{50\%}$ ). The lower this pH value, the stronger this distinct metal is bound to the sorbent, as for instance with Fe-oxides:  $\text{Pb} (\text{pH}_{50\%} = 3.1) > \text{Cu} (\text{pH}_{50\%} = 4.4) > \text{Zn} (\text{pH}_{50\%} = 5.4) > \text{Ni} (\text{pH}_{50\%} = 5.6) > \text{Cd} (\text{pH}_{50\%} = 5.8) > \text{Co} (\text{pH}_{50\%} = 6.0) > \text{Mn} (\text{pH}_{50\%} = 7.8)$  (Scheffer and Schachtschabel 1982).

**Table 7** Relative binding strength of metals on different sorbents (after Bunzl et al. 1976)

Substance	Relative binding strength
Clay minerals, zeolites	$\text{Cu} > \text{Pb} > \text{Ni} > \text{Zn} > \text{Hg} > \text{Cd}$
Fe, Mn-oxides and -hydroxides	$\text{Pb} > \text{Cr} = \text{Cu} > \text{Zn} > \text{Ni} > \text{Cd} > \text{Co} > \text{Mn}$
Organic matters (in general)	$\text{Pb} > \text{Cu} > \text{Ni} > \text{Co} > \text{Cd} > \text{Zn} = \text{Fe} > \text{Mn}$
Humic- and Fulvic acids	$\text{Pb} > \text{Cu} = \text{Zn} = \text{Fe}$
Peat	$\text{Cu} > \text{Pb} > \text{Zn} > \text{Cd}$
degraded peat	$\text{Cu} > \text{Cd} > \text{Zn} > \text{Pb} > \text{Mn}$

Corresponding to the respective sorbent, ion exchange capacity additionally depends on the pH value (Table 8).

**Table 8** Cation exchange capacity at pH 7 and their pH dependency (after Langmuir 1997)

Substance	CEC (meq/100g)	pH dependency
Clay minerals		
Kaolinite	3-15	high
Illite and Chlorite	10-40	low
Smectite Montmorillonite	80-150	rare or non existent
Vermiculite	100-150	negligible
Zeolites	100-400	negligible
Mn (IV) and Fe (III) Oxyhydroxides	100-740	high
Humic matter	100-500	high
synthetic cation exchangers	290-1020	low

Fig. 10 shows the pH-dependent sorption of metal cations; Fig. 11 the same for selected anions on iron hydroxide.

**Fig. 10** pH-dependent sorption of metal cations on iron hydroxide (after Drever 1997)

Fig. 11 pH-dependent sorption of anions on iron hydroxide (after Drever 1997)

#### Description of the ion exchange using the mass-action law

Assuming a complete reversibility of sorption, the ion exchange can be described by the mass-action law. The advantage of this approach is that virtually any number of species can interact at the surface of a mineral.

$$K_B^A = \frac{\{A^+ R^-\} \cdot \{B^+\}}{\{A^+\} \cdot \{B^+ R^-\}} = \frac{\{A^+ R^-\} / \{A^+\}}{\{B^+ R^-\} / \{B^+\}} \quad \text{Eq.(41.)}$$

with  $A^+, B^+$  monovalent ions  
 $R^-$  = exchanger

$K_x$  is the selectivity coefficient and is considered here as an equilibrium constant, even though, in contrast to complexation constants or dissociation constants, it depends not only on pressure, temperature, and ionic strength, but also on the respective solid phase with its specific properties of the inner and outer surfaces. Although to a lesser extent, it also depends on the way the reaction is written.

Thus, the exchange of sodium for calcium can be written as follows:

$$K_{Ca}^{Na} = \frac{\{NaX\} \{Ca^{2+}\}^{0.5}}{\{CaX_2\} \cdot \{Na^+\}} \quad \text{Eq.(42.)}$$

This expression is called the Gaines-Thomas convention (Gaines and Thomas 1953). Using the molar concentration instead the reaction description is called Vanselow convention (Vanselow 1932). Gapon (1933) proposed the following form:

$$\text{Na}^+ + \text{Ca} \frac{1}{2} \text{X} \leftrightarrow \text{NaX} \cdot \frac{1}{2} \text{Ca}^{2+}$$

$$K_{\text{Ca}}^{\text{Na}} = \frac{\{\text{NaX}\} \cdot \{\text{Ca}^{2+}\}^{0.5}}{\{\text{Ca} \frac{1}{2} \text{X}\} \cdot \{\text{Na}^+\}} \quad \text{Eq.(43.)}$$

### Important ion exchangers

Important ion exchangers and sorbents are, as can be seen from Table 7, clay minerals and zeolites (aluminous silicates), metal oxides (mainly iron and manganese oxides), and organic matter.

- Clay minerals consist of 1 to n layers of Si-O tetrahedrons and of 1 to n layers of aluminum hydroxide octahedral layers (gibbsite). Al very often replaces Si in the tetrahedral layer as well as Mg does for Al in the octahedral layer.
- As ion exchanger, zeolites play an important role in volcanic rocks and marine sediments.
- At the end of the weathering process, often iron and manganese oxides form. Manganese oxides usually form an octahedral arrangement resembling gibbsite. Hematite ( $\text{Fe}_2\text{O}_3$ ) and goethite ( $\text{FeOOH}$ ) also show a similar octahedral structure.
- Following Schnitzer (1986) 70 to 80% of organic matter are humic substances. These are condensed polymers composed of aromatic and aliphatic components, which form through the decomposition of living cells of plants and animals by microorganisms. Humic substances are hydrophilic, of dark color and show molecular masses of some hundreds to many thousands. They show widely differing functional groups being able to interact with metal ions. Humic substances (refractory organic acids) can be subdivided into humic and fulvic acids. Humic acids are soluble under alkaline conditions and precipitate under acid conditions. Fulvic acids are soluble under basic and acidic conditions.

Ion exchange or sorption can also occur on colloids, since colloids possess an electric surface charge, at which ions can be exchanged or sorptively bound. The proportion of colloids not caught in small pores preferentially utilizes larger pores, thus travelling faster than the water molecules in the aquifer (size-exclusion effect). That is why the colloid-bound contaminant transport is of such special importance.

Furthermore, there are synthetic ion exchangers, which are important for water desalination. They are composed of organic macromolecules. Their porous network, made up from hydrocarbon chains, may bind negatively charged groups (cation exchanger) or positively charged groups (anion exchanger). Cation exchangers are based mostly on sulfo-acidic groups with an organic group, anion exchangers are based on substituted ammonium groups with an organic group.

### Surface charges

The cation-exchange capacity of clay minerals is in a range of 3 to 150 meq/100g (Table 8). These extremely high exchange capacities are due to two physical reasons:

- extremely large surfaces
- electric charges of the surfaces

These electric charges can be subdivided into:

- permanent charges
- variable charges

Permanent surface charges can be related to the substitution of metals within the crystal lattice (isomorphism). Since usually metals are replaced by other metals of a lower charge, this results in an overall deficit in positive charge for the crystal. A negative potential forms at the surface causing positively charged metals to sorb. The surface charges of clay minerals can be predominantly related to isomorphism, therefore they are permanent to a great portion. However, this is not true for all clay minerals; for kaolinite the permanent charge is less than 50% (Bohn et al., 1979).

Besides the permanent charge, there are variable surface charges, which depend on the pH of the water. They arise from protonation and deprotonation of functional groups at the surface. Under acid conditions, protons are sorbed on the functional groups that cause an overall positive charge on the surface. Thus the mineral or parts of it behave as an anion exchanger. With high pH, the oxygen atoms of the functional groups stay deprotonized and the mineral, or parts of it, shows an overall negative charge; therefore cations can be sorbed.

For every mineral there is a pH value at which the positive charge caused by protonization equals the negative charge caused by deprotonization, so that the overall charge is zero. This pH is called the  $\text{pH}_{\text{PZC}}$  (Point of Zero Charge). If only deprotonization and protonization have an influence on the surface charge this value is called ZPNPC (zero point of net proton charge) or IEP (iso-electric point). This point is around pH 2.0 for quartz, around pH 3.5 for kaolinite, for goethite, magnetite, and hematite approximately between pH 6 and 7, and for corundum around pH 9.1 (Drever 1997). Fig. 12 shows the pH-dependent sorption behavior of iron hydroxide surfaces. The overall potential of the pH-dependent surface charge does not depend on the ionic strength of water.

Natural systems are a mixture of minerals with permanent and variable surface charge. Fig. 13 shows the general behavior in relation to anion and cation sorption. At values exceeding pH 3 the anion exchange capacity decreases considerably. Up to pH 5 the cation exchange capacity is constant, rising extremely at higher values.

Fig. 12 pH-dependent sorption behavior of iron hydroxide surfaces after binding of  $H^+$  under acid and  $OH^-$  ions under alkaline conditions (after Sparks 1986).

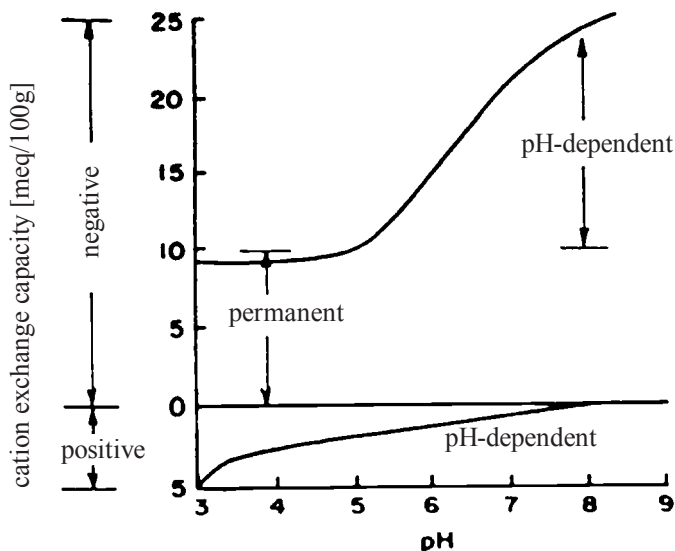

Fig. 13 Cation and anion exchange behavior of minerals as a function of pH (after Bohn et al. 1979); "negative" and "positive" relates to the charge of the surfaces, so that "negatives" are cation exchanger and "positives" anion exchanger.

#### 1.1.4.2.3. Mathematical description of the sorption

Numerous equations are used to describe experimental data obtained for interactions between liquid and solid phases. These equations range from simple empirical equations (sorption isotherms) to complicated mechanistic models based

on surface complexation for the determination of electric potentials, e.g. constant-capacitance, diffuse-double layer, triple layer, and charge distribution multi-site complexation (CD-MUSIC) model.

### Empirical models - sorption isotherms

Sorption isotherms are the depiction of sorption-interactions using simple empirical equations. Initially, the measurements were done at constant temperature, that is why the term “isotherm” was introduced.

### Linear-regression isotherm (Henry isotherm)

The most simple form of a sorption isotherm is the linear-regression equation.

$$C^* = K_d \cdot C \quad \text{Eq.(44.)}$$

with  $C^*$  = mass of substance sorbed at a mineral (mg/kg)

$K_d$  = distribution coefficient

$C$  = concentration of the substance in water (mg/L)

Linear-sorption terms have the advantage of simplicity and they can be converted into a retardation factor  $R_f$ , so that the general transport equation can be easily expanded by applying the correction term:

$$R_f = 1 + \frac{B_d}{q} \cdot \frac{C^*}{C} = 1 + \frac{B_d}{q} \cdot K_d \quad \text{Eq.(45.)}$$

with  $B_d$  = bulk density

$q$  = water content

A severe disadvantage is that the relation is linear, so that there is no upper limit to the sorption.

### Freundlich isotherms

Using the Freundlich isotherm, an exponential relation between sorbed and dissolved molecules can be described:

$$C^* = K_d \cdot C^n \quad \text{Eq.(46.)}$$

$$R_f = 1 + \frac{B_d}{q} \cdot n \cdot K_d \cdot C^{n-1} \quad \text{Eq.(47.)}$$

A further empirical constant  $n$  is introduced, which is usually less than 1. The Freundlich isotherm is based on a model of a multi-lamellar coating of the solid surface assuming *a priori* that all sites with the largest binding energy (of electrostatic forces) are occupied (steep section of the curve). Only when significantly increasing the concentration of analyte in solution, sorption will also occur at additional sites with lower binding energy (flattening of the curve).

Using the Freundlich isotherm, a retardation factor can be calculated as with the linear Henry isotherm. Advantageous in comparison to the linear model is that an upper limit for sorption capacity is defined.

### Langmuir isotherm

The Langmuir isotherm was developed to describe sorbents with a limited number of sorption sites on their surface:

$$C^* = \frac{a \cdot b \cdot C}{1 + a \cdot C} \quad \text{Eq.(48.)}$$

with  $a$  = sorption constant

$b$  = maximum sorbable mass of the substance (mg/kg)

$$Rf = 1 + \frac{Bd}{q} \cdot \left[ \frac{a \cdot b}{(1 + a \cdot C)^2} \right] \quad \text{Eq.(49.)}$$

From the scientific point of view, however, all approaches in the sense of the  $K_d$  concept (Henry, Freundlich or Langmuir isotherm) are unsatisfactory, since the complex exchange processes including surface reactions can not be described by empirical fitting parameters. Boundary conditions like pH value, redox potential, ionic strength, or competition of individual sorbents in solution for the same binding sites are not considered.

Thus, even though the  $K_d$  concept is frequently applied, often because no parameters for deterministic or mechanistic approaches are available, results from laboratory and field experiments are seldom transferable to real systems. The  $K_d$  concept could only provide a suitable prognosis model if no changes in boundary conditions are to be expected.

### Mechanistic models for surface complexation

Surface complexation is a theory to describe the phenomenon of sorption. At the surface of iron, aluminum, silica, and manganese hydroxides as well as humic substances, there are cations that are not completely surrounded by oxygen ions in contrast to the cations in the interior of the crystal lattice. Because of their valence electrons they may bind water molecules. After sorption, the protons of these water molecules rearrange such that every surface oxygen atom binds only one proton. The second proton binds to oxygen atoms in the crystal lattice (Fig. 14). Thus, a layer of functional groups is formed containing O, S, or N on the surface of the mineral (double layer).

After Stumm and Morgan (1996) the reaction can be described as follows:

Here, GH is a functional group as  $(R-COOH)_n$  or  $(=AlOH)_n$ . The capability of functional groups to form complexes strongly depends on the acid-base behavior and, hence, on pH changes in an aquatic system.

Similar to complexes in solution, surface complexes can be distinguished in inner-spherical complexes (e.g. phosphate, fluoride, copper), where the ion is directly bound to the surface, and outer-spherical (e.g. sodium, chloride) complexes where the ion is covered by a hydration sleeve with electrostatic binding. The inner-sphere complex is much stronger and independent of electrostatic forces, i.e. a cation can also be sorbed on a positively charged surface (Drever 1997).

On this basis, four models will be discussed, which enable a calculation of the electrical potential, namely the constant-capacitance, the diffuse-double-layer, the triple-layer and the charge distribution multi-site complexation model.

Incomplete Coordination

Coordination Sphere-Completed  
by Water Molecules

Proton Reorganisation for Forming  
of Surface-Hydroxyl-Groups

Fig. 14 The process of surface complexation (after Drever 1997)

### Diffuse Double-Layer Model (DDLDM)

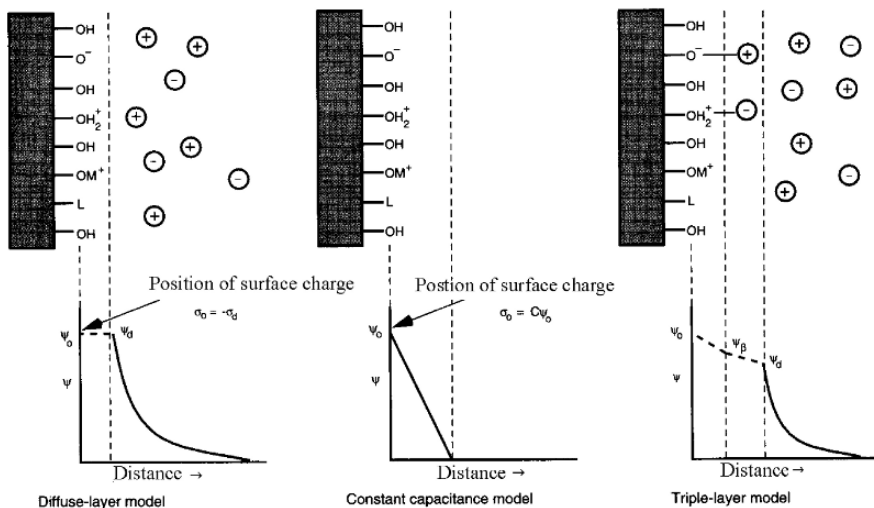

This model is based on the Gouy-Chapman theory (diffuse double-layer theory). The theory states that in the area of the boundary layer between solid and aqueous phase, independently of the surface charge, increased concentrations of cations and anions within a diffuse layer exists because of electrostatic forces. In contrast to the constant-capacitance model, the electrical potential does not change up to a certain distance from the phase boundaries and is not immediately declining in a linear manner (Fig. 15 left). Diffusion counteracts these forces, leading to dilution with increasing distance from the boundary. This relation can be described physically by the Poisson-Boltzmann equation.

### Constant-Capacitance Model (CCM)

The constant-capacitance model assumes that the double layer on the solid-liquid phase boundary can be regarded as a parallel-plate capacitor (Fig. 15 middle).

### Triple-Layer Model (TLM)

While CCM and DDLDM assume that all ions are at one plane, the triple layer includes different planes, in which the surface complexes are bound. In the original version of Davis et al. (1987) the protons and hydroxide ions are bound at the layer ( $\alpha$ -plane) close to the phase boundary, whereas inner-sphere complexes are bound in a  $\beta$ -plane somewhat dislodged. Both planes are assumed as constant-capacity layers. The range outside the  $\beta$ -plane containing the outer-sphere complexes is modeled as a diffuse layer (Fig. 15 right).

**Fig. 15** Idealized distribution of the electrical potential in the vicinity of hydrated oxide surfaces after (from left to right) the diffuse-layer model, the constant-capacitance model and the triple-layer model (after Drever 1997).

### Charge distribution multi-site complexation model (CD-MUSIC)

An advanced version of a triple layer model is the charge distribution multi-site complexation model (Hiemstra and Van Riemsdijk 1996, 1999). The assignment of the three layers is the same, only the nomenclature is different; the numbers 0, 1, 2 are assigned to the o-, the  $\beta$ -, and the d plane, respectively. The clear advantage of the CD-MUSIC model is that it takes into account the chemical composition of the crystal surface which can be investigated, e.g. by in-situ infrared-spectroscopy, EXAFS (extended x-ray absorption fine structure) investigations, or TEM (Transmission Electron Microscopy). Thus, the relevant parameters are not free fitting parameters as in the three models described above (DDLm, CCM, TLM) but are constrained by measured physical or chemical data. Cation and anion sorption are treated in the same way based on Pauling's concepts of charge distribution of ions. Furthermore, the CD-MUSIC model can take into account competitive sorption of two or more ligands. However, CD-MUSIC can not be applied to amorphous solids.

## **1.1.5 Interactions in the liquid phase**

### **1.1.5.1 Complexation**

Complexation has a significant influence on dissolution and precipitation of minerals as already described in chapter 1.1.4.1.3. In contrast to the dissolution of minerals, complexation is a homogeneous reaction. It can be described by the mass-action law. The complexation constant,  $K$ , gives information about the complex stability. Large complex constants indicate a strong tendency for complexation, or high complex stability.

Positively charged, zero-charged, and negatively charged complexes can be distinguished. Contaminants for instance have an especially high mobility if they occur as zero-charged complexes, since they undergo almost no exchange processes, whereas (positively or negatively) charged complexes show interactions with other ions and solid surfaces.

A complex can be defined as a coordination compound of a positively charged part with a negatively charged part, the ligand. The positively charged part is usually a metal ion or hydrogen, but may also be another positively charged complex. Ligands are molecules, which have at least one free pair of electrons (bases). This ligand can either be free anions like  $F^-$ ,  $Cl^-$ ,  $Br^-$ ,  $I^-$  or negatively charged complexes as  $OH^-$ ,  $HCO_3^-$ ,  $CO_3^{2-}$ ,  $SO_4^{2-}$ ,  $NO_3^-$ , and  $PO_4^{3-}$ .

From the periodic table of elements the following elements can be possible ligands:

Group	4	5	6	7
	C	N	O	F
		P	S	Cl
		As	Se	Br
			Te	I

Beside these inorganic ligands there are also organic ligands like humic or fulvic acids, which occur naturally in almost all waters, but also NTA and EDTA, which enter the hydrosphere as phosphate substitutes in detergents (Bernhardt et al. 1984) and can mobilize metals.

The complex binding can be electrostatic, covalent, or a combination of both. Electrostatically bound complexes, where the metal atom and the ligand are separated by one or more hydrogen molecules, are called outer-sphere complexes. They are less stable and are formed when hard cations come into contact with hard ligands (Table 9).

The Pearson concept of “hard” and “soft” acids and bases considers the number of electrons in the outer shell. Elements with a saturated outer shell and low tendency for polarization (noble gas configuration) are called “hard” acids, while elements with only partially filled outer shell, low electronegativity, and high tendency for polarization are “soft” acids.

Inner-sphere complexes, with covalent bounds between a metal atom and a ligand, form from soft metal atoms and soft ligands or soft metal atoms and hard ligands or hard metal atoms and soft ligands and are much more stable.

**Table 9** Classification of metal ions into A and B- type and after the Pearson concept into hard and soft acids with preferred ligands (after Stumm and Morgan 1996)

Metal cations type A („hard spheres“)	Transition metal cations	Metal cations type B („soft spheres“)
$H^+$ , $Li^+$ , $Na^+$ , $K^+$ , $Be^{2+}$ , $Mg^{2+}$ , $Ca^{2+}$ , $Sr^{2+}$ , $Al^{3+}$ , $Sc^{3+}$ , $La^{3+}$ , $Si^{4+}$ , $Ti^{4+}$ , $Zr^{4+}$ , $Th^{4+}$	$V^{2+}$ , $Cr^{2+}$ , $Mn^{2+}$ , $Fe^{2+}$ , $Co^{2+}$ , $Ni^{2+}$ , $Cu^{2+}$ , $Ti^{3+}$ , $V^{3+}$ , $Cr^{3+}$ , $Mn^{3+}$ , $Fe^{3+}$ , $Co^{3+}$	$Cu^+$ , $Ag^+$ , $Au^+$ , $Tl^+$ , $Ga^+$ , $Zn^{2+}$ , $Cd^{2+}$ , $Hg^{2+}$ , $Pb^{2+}$ , $Sn^{2+}$ , $Tl^{3+}$ , $Au^{3+}$ , $In^{3+}$ , $Bi^{3+}$
according to Pearson concept		
hard acids	Transition range	soft acids
all metal cations type A plus $Cr^{3+}$ , $Mn^{3+}$ , $Fe^{3+}$ , $Co^{3+}$ , $UO^{2+}$ , $VO^{2+}$	all divalent transition metal cations plus $Zn^{2+}$ , $Pb^{2+}$ , $Bi^{3+}$	all metal cations type B except for $Zn^{2+}$ , $Pb^{2+}$ , $Bi^{3+}$
preference for ligand atom		
$N \gg P$ , $O \gg S$ , $F \gg Cl$		$P \gg N$ , $S \gg O$ , $Cl \gg F$

Chelates are complexes with ligands that form more than one bond with the positively charged metal ion (multidentate ligands). Such complexes show an especially high stability. Complexes with more than one metal atom are called multi- or polynuclear complexes.

By means of complexation, a metal can occur in normally unknown or rare oxidation states. For instance,  $Co^{3+}$ , being a strong oxidizing agent, is normally not stable in aqueous solutions, but it is stable as  $Co(NH_3)_6^{3+}$ . Furthermore, complexation can prevent disproportionation, as in the case of  $Cu^+$  e.g., which converts into  $Cu^{2+}$  and  $Cu(s)$  in an aqueous solution, although it is stable as  $Cu(NH_3)_2^+$ .

Deducting general statements about the stability of different complexes e.g. from the ionic strength or dividing compounds into generally well and poor

chelating agents based on the periodic table of elements is problematic. Such generalizations do not appear practical, because the tendency of elements to form complexes critically depends on the corresponding ligand, as Table 10 shows for some examples. And last, but not least, the concentration of the ligand in the solution (main or trace element) is of crucial importance.

**Table 10 Complexation constants (logK) for hydroxide, carbonate, and sulfate complexes (data from WATEQ4F and (\*)LLNL data base); Me = metal cations, n = oxidation state of the cations (n = 1, 2, 3)**

### 1.1.5.2 Redox processes

Together with acid-base reactions, where a proton transfer occurs (pH-dependent dissolution/ precipitation, sorption, complexation) redox reactions play an important role for all interactions in aqueous systems. Redox reactions consist of two partial reactions, oxidation and reduction, and can be characterized by oxygen or electron transfer. Many redox reactions in natural aqueous systems can actually not be described by thermodynamic equilibrium equations, since they have slow kinetics. If a redox reaction is considered as a transfer of electrons, the following general reaction can be derived:

with n = number of electrons,  $\text{e}^-$ .

#### 1.1.5.2.1. Measurement of the redox potential

Inserting an inert but highly conductive metal electrode into an aqueous solution allows electrons to transfer both from the electrode to the solution and vice versa. A potential difference (voltage) builds up, which can be determined in a current-less measurement. Per definition, this potential is measured relative to the standard

hydrogen electrode with  $P(H_2) = 100 \text{ kPa}$ ,  $pH = 0$ , temperature =  $25^\circ\text{C}$  and a potential of

$$E^\circ \left( \frac{H^+}{H_2} \right) = 0 \text{ mV} \quad \text{Eq.(52.)}$$

In the aqueous solution, the potential is measured as an integral over all existing redox species (mixed potential).

Since the use of the standard hydrogen electrode in the field would be very tedious and dangerous, other reference electrodes are used. Those reference electrodes have a defined Eigenpotential,  $E_B$ , which is added to the determined value  $E_M$ , to obtain the solution potential, or  $E_H$ , with reference to the standard hydrogen electrode. Mostly  $Ag/AgCl$  or mercury chloride ( $Hg_2Cl_2$ )/ platinum electrodes are used as reference electrodes. The advantage of  $Ag/AgCl$  electrodes is the fast response rate, whereas the mercurial chloride/platinum-electrode has a slower response rate but yields higher precision. Faster response times and higher sensitivities can be achieved with microelectrodes where currents are smaller and relative diffusion current per surface area is enhanced.

In practice, the measurement of the redox potential is, independent of the reference electrode, highly problematic. Contamination and memory effects are a common problem with all types of electrodes. Furthermore, many natural waters are likely not to be in thermodynamical redox equilibrium and redox species are present in concentrations too low to give an electrode response (Nordstrom and Munoz 1994). Therefore redox measurements should be aborted after 1 hour if no steady state is reached. The result obtained from the measurement in that case is, that the water is in thermodynamic disequilibrium with regard to its redox species. For thermodynamic modeling this means that species distribution can not be derived from total element concentrations via the measured redox potential. If redox-sensitive elements are decisive for the model, each redox pair has to be determined individually by analytical speciation methods.

#### 1.1.5.2.2. Calculation of the redox potential

The equilibrium redox potential can be calculated from the following Nernst equation:

$$E_h = E^\circ + \frac{R \cdot T}{n \cdot F} \ln \frac{\{ox\}}{\{red\}} \quad \text{Eq.(53.)}$$

$E^\circ$  = standard redox potential of a system where the activities of the oxidized species equal the activities of the reduced species

$R$  = ideal gas constant ( $8.3144 \text{ J/K mol}$ )

$T$  = absolute temperature (K)

$n$  = number of transferred electrons ( $e^-$ )

$F$  = Faraday constant ( $96484 \text{ C/mol} = \text{J/V mol}$ )

$\{ox\}$  = activity of the oxidized species

$\{red\}$  = activity of the reduced species

Eq. 53 describes the calculation of individual redox potentials, unlike the measured redox potential, which may be a mixed potential of various redox reactions not in equilibrium.

When citing redox potential values it is important to provide the corresponding redox reaction equation since reversing the equation causes a change in the sign.

Table 11 shows some redox-sensitive elements in the periodic system of the elements, Table 12 depicts standard potentials for some important redox pairs in aqueous systems.

**Table 12 Standard potentials and  $E_H$  in volts for some important redox couples in aqueous systems at 25°C (modified after Langmuir 1997)**

Reaction	$E^\circ$ Volt	$E_H$ Volt / pH 7.0	assumptions
$4H^+ + O_{2(g)} + 4e^- = 2 H_2O$	1.23	0.816	$P_{O_2}=0.2$ bar
$NO_3^- + 6 H^+ + 5e^- = 0.5 N_{2(g)} + 3 H_2O$	1.24	0.713	$10^{-3}$ mol N, $P_{N_2}=0.8$ bar
$MnO_2 + 4 H^+ + 2 e^- = Mn^{2+} + 2 H_2O$	1.23	0.544	$10^{-4.72}$ mol Mn
$NO_3^- + 2 H^+ + 2e^- = NO_2^- + H_2O$	0.845	0.431	$NO_3^- = NO_2^-$
$NO_2^- + 8 H^+ + 6 e^- = NH_4^+ + 2 H_2O$	0.892	0.340	$NO_3^- = NH_4^+$
$Fe(OH)_3 + 3 H^+ + e^- = Fe^{2+} + 3 H_2O$	0.975	0.014	$10^{-4.75}$ mol Fe
$Fe^{2+} + 2 SO_4^{2-} + 16 H^+ + 14 e^- = FeS_2 + 8 H_2O$	0.362	-0.156	$10^{-4.75}$ mol Fe, $10^{-3}$ mol S
$SO_4^{2-} + 10 H^+ + 8e^- = H_2S_{(aq)} + 4 H_2O$	0.301	-0.217	$SO_4^{2-} = H_2S$
$HCO_3^- + 9 H^+ + 8 e^- = CH_{4(aq)} + 3 H_2O$	0.206	-0.260	$HCO_3^- = CH_4$
$H^+ + e^- = 0.5 H_{2(g)}$	0.0	-0.414	$P_{H_2}=1.0$ bar
$HCO_3^- + 5 H^+ + 4 e^- = CH_2O (DOM) + 2 H_2O$	0.036	-0.482	$HCO_3^- = CH_2O$

The equation for the calculation of redox potentials (Eq. 53) derives from the equation of the Gibbs free energy (compare also Eq. 6).

$$G = G^0 - R \cdot T \cdot \ln \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(54.)}$$

$$E_H = -\frac{G}{n \cdot F} \quad \text{Eq.(55.)}$$

$$-\frac{G}{n \cdot F} = -\frac{G^0}{n \cdot F} - \frac{R \cdot T}{n \cdot F} \cdot \ln \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(56.)}$$

$$E_H = E^0 - \frac{R \cdot T}{n \cdot F} \cdot \ln \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(57.)}$$

Eq. 53 is obtained from Eq. 57 by inversion of numerator and denominator within the argument of the logarithm. That leads to the minus sign in front of the logarithm.

For standard conditions of 25°C and inserting standard values for the gas constant and the Faraday constant, a simplified form ensues:

$$E_H = E^0 - \frac{0.0591}{n} \cdot \log \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(58.)}$$

Dealing with pH-dependent redox reactions, as e.g. the oxidation of Cl<sup>-</sup> to Cl<sub>2</sub> by permanganate at pH 3, the number of protons used and formed must be considered.

$$E_H = E^0 - 2.303 \cdot \frac{m \cdot R \cdot T}{n \cdot F} \cdot \text{pH} - 2.30 \cdot \frac{R \cdot T}{n \cdot F} \cdot \log \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(59.)}$$

The factor 2.303 results from the conversion of the natural logarithm to the common logarithm. Since redox potentials cannot be used directly in thermodynamic programs (unit: volt!), the pE value was introduced for mathematical convenience. Analogous to the pH value the pE value is the negative common logarithm of the electron activity. Thus, it is calculated using a hypothetical activity, respectively concentration of electrons, which is actually not present in water. For the calculation of the pE value Eq. 51 is used and the following equation is obtained for the equilibrium constant K:

$$\log K = \log \frac{\{\text{red}\}}{\{\text{ox}\} \{\bar{e}\}^n} = \log \frac{\{\text{red}\}}{\{\text{ox}\}} + \log \frac{1}{\{\bar{e}\}^n} = \log \frac{\{\text{red}\}}{\{\text{ox}\}} - n \cdot \log \{\bar{e}\} \quad \text{Eq.(60.)}$$

$$-n \cdot \log \{e^-\} = \log K - \log \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(61.)}$$

$$-\log \{e^-\} = \frac{1}{n} \log K - \frac{1}{n} \log \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(62.)}$$

$$pE = \frac{1}{n} \log K - \frac{1}{n} \log \frac{\{\text{red}\}}{\{\text{ox}\}} \quad \text{Eq.(63.)}$$

The conversion from pE to the measured redox potential  $E_H$  follows from:

$$pE = -\log \{e^-\} = \frac{F}{2.303 \cdot R \cdot T} \cdot E_H \quad \text{Eq.(64.)}$$

F, R, and T=25°C inserted, the following simplified form results [ $E_H$  in V]:

$$pE \approx 16.9 \cdot E_H \quad \text{Eq.(65.)}$$

For the system  $H_2/H^+$  the following is applicable:

$$E_H = E^\circ \left( \frac{H^+}{H_2} \right) + \frac{R \cdot T}{n \cdot F} \cdot \ln \frac{\{H^+\}^2}{\{H_2\}} \quad \text{Eq.(66.)}$$

$$E_H = 0 + \frac{R \cdot T}{n \cdot F} \cdot \ln \{H^+\}^2 - \frac{R \cdot T}{n \cdot F} \cdot \ln \{H_2\} \quad \text{Eq.(67.)}$$

$$E_H = 0 + \frac{2.303 \cdot R \cdot T}{2 \cdot F} \cdot 2 \cdot \log \{H^+\} - \frac{2.303 \cdot R \cdot T}{2 \cdot F} \cdot \log \{H_2\} \quad \text{Eq.(68.)}$$

$$E_H = 0 - \frac{2.303 \cdot R \cdot T}{F} \cdot pH - \frac{2.303 \cdot R \cdot T}{2 \cdot F} \cdot \log \{H_2\} \quad \text{Eq.(69.)}$$

Inserting standard values for R and F, as well as T =25°C and  $P(H_2) = 1 \cdot 10^5$  Pa, it follows:

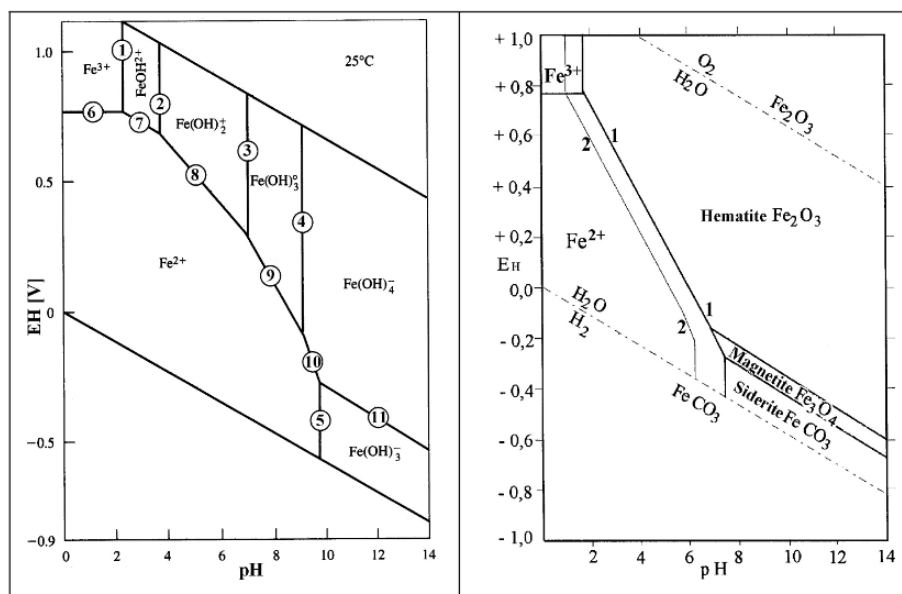

$$E_H = -0.0591 \cdot pH \quad \text{Eq.(70.)}$$

An increase or decrease of one pH unit causes a decrease or increase, respectively, of the Nernst voltage by 59.1 mV.

### 1.1.5.2.3. Presentation in predominance diagrams

The presentation of the predominant species for each redox system is called stability (or better) predominance diagram (also called  $E_H$ -pH or pE-pH diagrams). Predominance diagrams are extremely dependent on which elements in which concentrations and at which ionic strength are considered. Usually only the species dissolved in water are depicted (Fig. 16 left). However, if the concentration or activity falls below certain user-defined limits, often the (predominant) precipitating mineral phase is outlined instead (Fig. 16 right). The lines bordering individual predominance ranges show the pE/pH conditions, under which the activities of two neighboring species equal each other.

How such a  $E_H$ -pH diagram can be determined analytically is explained below using the example of the Fe-O<sub>2</sub>-H<sub>2</sub>O diagram shown in Fig. 16 left. In each  $E_H$ -pH diagram the occurrence of the aqueous species is limited by the stability field of water. Above this field H<sub>2</sub>O converts to elementary oxygen, below this field to elementary hydrogen (also see Fig. 17).

**Fig. 16** Left:  $E_H$ -pH diagram for the system Fe-O<sub>2</sub>-H<sub>2</sub>O (at 25°C, the numbers 1-11 correspond to the reaction equations described in the text for the calculation of the stability fields, modified after Langmuir 1997) Right:  $E_H$ -pH diagram for the system Fe-O<sub>2</sub>-H<sub>2</sub>O-CO<sub>2</sub> (at 25°C,  $P(\text{CO}_2) = 10^{-2}$  atm), for fields where the total activity is  $< 10^{-6}$  (1) resp.  $< 10^{-4}$  (2) mol/L the predominant, precipitating mineral phase is outlined (modified after Garrels and Christ 1965).

According to Eq. 71 each oxygen concentration is (analytically) assigned to a certain hydrogen content. This means that oxygen saturated (i.e. completely oxidized) water with the partial pressure of  $P(\text{O}_2) = 1 \cdot 10^5$  Pa is in equilibrium with

hydrogen with a partial pressure of  $P(\text{H}_2) = 10^{-42.6} \cdot 10^5 \text{ Pa}$ . The other way round hydrogen saturated (completely reduced) water is in equilibrium with oxygen of a partial pressure  $P(\text{O}_2) = 10^{-85.2} \cdot 10^5 \text{ Pa}$ .

$$K = \frac{\{\text{pH}_2\}^2 \cdot \{\text{pO}_2\}}{\{\text{H}_2\text{O}\}^2} = 10^{-85.2} \quad \text{Eq.(71.)}$$

The diagram's vertical boundaries (Fig. 16, number 1-5) are reactions that describe a dissolution in water (hydrolysis) independent of the  $E_{\text{H}}$  value. The boundaries of the respective predominance fields are calculated via the equilibrium constants for the conversion of the species at each side of the boundary line into each other.

No.	Reaction couples	Reaction equation	$-\log K = \text{pH}$
1	$\text{Fe}^{3+}/\text{FeOH}^{2+}$	$\text{Fe}^{3+} + \text{H}_2\text{O} = \text{FeOH}^{2+} + \text{H}^+$	2.19
2	$\text{FeOH}^{2+}/\text{Fe}(\text{OH})_2^+$	$\text{FeOH}^{2+} + \text{H}_2\text{O} = \text{Fe}(\text{OH})_2^+ + \text{H}^+$	3.48
3	$\text{Fe}(\text{OH})_2^0/\text{Fe}(\text{OH})_3^0$	$\text{Fe}(\text{OH})_2^+ + \text{H}_2\text{O} = \text{Fe}(\text{OH})_3^0 + \text{H}_2\text{O}$	6.89
4	$\text{Fe}(\text{OH})_3^0/\text{Fe}(\text{OH})_4^-$	$\text{Fe}(\text{OH})_3^0 + \text{H}_2\text{O} = \text{Fe}(\text{OH})_4^- + \text{H}^+$	9.04
5	$\text{Fe}^{2+}/\text{Fe}(\text{OH})_3^-$	$\text{Fe}^{2+} + 3\text{H}_2\text{O} = \text{Fe}(\text{OH})_3^- + 3\text{H}^+$	9.08

The conversion of  $\text{Fe}^{3+}$  into  $\text{Fe}^{2+}$  (Fig. 16, number 6), is a pure redox reaction, independent of the pH-value (horizontal boundary). It is calculated after Eq. 58:

$$E_{\text{H}} = E^{\circ} - \frac{0.0591}{n} \cdot \log \frac{\{\text{red}\}}{\{\text{ox}\}}$$

For the calculation of the boundary line the activity of both species is equal, i.e.  $\{\text{red}\} = \{\text{ox}\}$ . Thus the argument of the logarithm is 1 and the logarithm is 0, i.e.  $E_{\text{H}} = E_0$ .

No.	Reaction couples	Reaction equation	$E_0 \text{ (V)}$	$E_{\text{H}} = E_0$
6	$\text{Fe}^{3+}/\text{Fe}^{2+}$	$\text{Fe}^{3+} + \text{e}^- = \text{Fe}^{2+}$	0.770	0.770

The diagonal boundaries display species transformations, which depend on pH and  $E_{\text{H}}$ . After Eq. 59

$$E_{\text{H}} = E^{\circ} - 2.303 \cdot \frac{m \cdot R \cdot T}{n \cdot F} \cdot \text{pH} - 2.303 \cdot \frac{R \cdot T}{n \cdot F} \cdot \log \frac{\{\text{red}\}}{\{\text{ox}\}}$$

the calculation of the boundary line ( $\{\text{ox}\} = \{\text{red}\}$ ) follows:

$$E_{\text{H}} = E^{\circ} - \frac{0.0591 \cdot m}{n} \cdot \text{pH}$$

with  $m$ = number of protons used or formed in the reaction

No	Reaction couples	Equation of reaction	E <sub>0</sub> (V)	Equation for boundary line
7	FeOH <sup>2+</sup> /Fe <sup>2+</sup>	FeOH <sup>2+</sup> + H <sup>+</sup> + e <sup>-</sup> = Fe <sup>2+</sup> + H <sub>2</sub> O	0.899	0.899-0.0591 pH

9	Fe(OH) <sub>3</sub> <sup>0</sup> /Fe <sup>2+</sup>	Fe(OH) <sub>3</sub> <sup>0</sup> + 3H <sup>+</sup> + e <sup>-</sup> = Fe <sup>2+</sup> + 3H <sub>2</sub> O	1.513	1.513-0.177 pH
10	Fe(OH) <sub>4</sub> <sup>-</sup> /Fe <sup>2+</sup>	Fe(OH) <sub>4</sub> <sup>-</sup> + 4H <sup>+</sup> + e <sup>-</sup> = Fe <sup>2+</sup> + 4H <sub>2</sub> O	2.048	2.048-0.236 pH
11	Fe(OH) <sub>4</sub> <sup>-</sup> /Fe(OH) <sub>3</sub> <sup>0</sup>	Fe(OH) <sub>4</sub> <sup>-</sup> + H <sup>+</sup> + e <sup>-</sup> = Fe(OH) <sub>3</sub> <sup>0</sup> + H <sub>2</sub> O	0.308	0.308-0.0591 pH

How E<sub>H</sub>-pH-diagrams change if besides O<sub>2</sub>, H<sub>2</sub>O and CO<sub>2</sub> other species, as e.g. hydrogen carbonate or sulfate, are also considered can be modeled numerically in chapter 3.1.3.1 and 3.1.3.2. E<sub>H</sub>-pH diagrams can also be used as a first approximation to characterize natural waters (Fig. 17). However, the mentioned problems concerning the precision and uncertainties of E<sub>H</sub> measurements must be taken into account (chapter 1.1.5.2.1).

Partial pressure or fugacity diagrams provide another possibility of presentation. Analogous to the activity for the concentration the fugacity is an effective pressure, which describes the tendency of a gas for volatilization from a phase (Latin *fugere* = flee). Under low-pressure conditions, the fugacity equals the partial pressure. In fugacity diagrams the species distribution species is displayed as dependent on the partial pressure of e.g. O<sub>2</sub>, CO<sub>2</sub> or S<sub>2</sub> (Fig. 18). Furthermore there is the possibility to show the species distribution in 3-D models (Fig. 19). Such illustrations easily get confusing though.

Fig. 17 Classification of natural waters under various E<sub>H</sub>/pH conditions (modified after Wedepohl 1978)

Fig. 19 3-D illustration of a fugacity diagram of some iron compounds as a function of  $P(O_2)$ ,  $P(CO_2)$  and  $P(S_2)$  at 25°C and a total pressure of 1 atm or higher (modified after Garrels and Christ 1965)

#### 1.1.5.2.4. Redox buffer

Analogous to acid-base-buffers, there are also buffers in the redox system, which can level strong variations of the pE value. Yet, the redox equilibrium in groundwater can be easily disturbed (Käss 1984). In Fig. 20 some redox buffers are depicted in a pE/pH diagram together with a rough division of groundwaters into four ranges. Field 1 characterizes near-surface water with a short residence time, free oxygen, and no degradation processes. Most groundwaters lie in the range of field 2 without free oxygen, but also without significant reduction of sulfate. Groundwaters with long residence times, a high proportion of organic substances and high concentrations of sulfide plot into the range of field 3. Field 4 contains young mud and peat waters, where a fast degradation of organic material occurs under anaerobic conditions.

**Fig. 20** Redox buffer and subdivision of natural groundwaters into 4 redox ranges within the stability field of water; black dashed lines indicate the boundaries of the four redox ranges (after Drever 1997)

#### 1.1.5.2.5. Significance of redox reactions

Oxidation and reduction processes play a major role both in the saturated zone as well as in the unsaturated zone. Within the unsaturated zone there is generally sufficient oxygen from the gas phase to guarantee high redox potentials (500 to 800 mV) in the water. Despite of that, reducing or partly reducing conditions might occur in small cavities (micro-milieus). In aquifers close to the surface

oxidizing conditions usually prevail, too. Thus low redox potentials in such aquifers can indicate anthropogenic contamination.

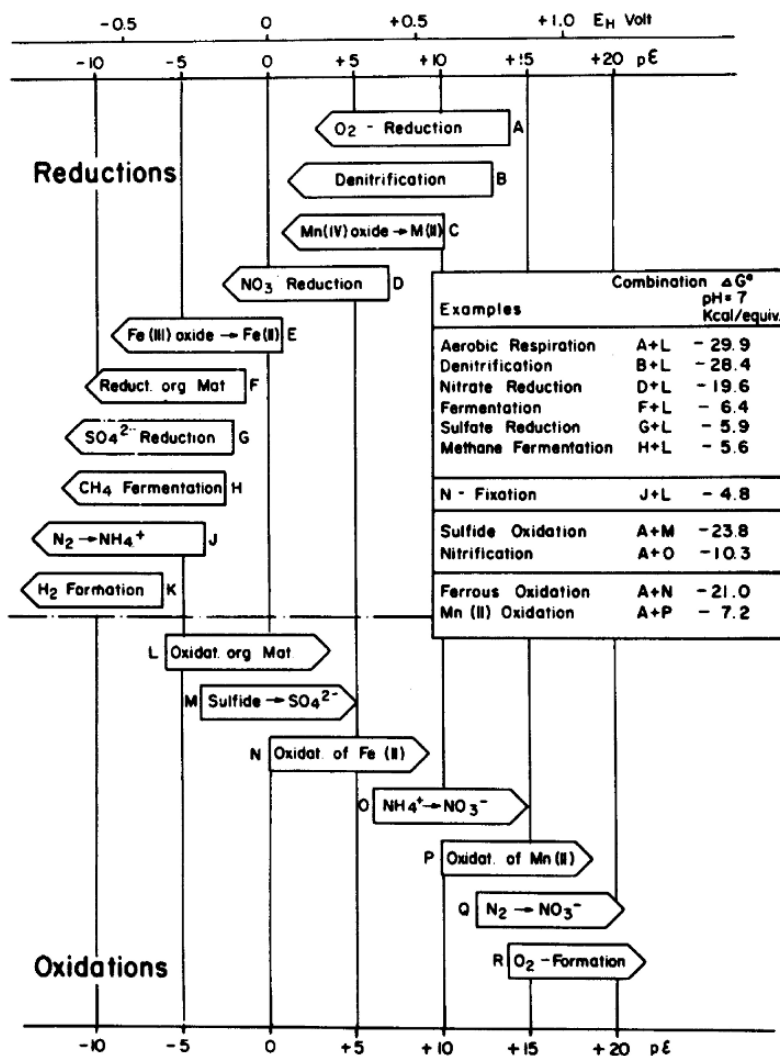

Fig. 21 Microbially catalyzed redox reactions dependent on pE/E<sub>H</sub> conditions (after Stumm and Morgan 1996)

With increasing depth, even under natural geogenic conditions, oxygen contents and consequently the redox potential in groundwater decreases. Micro-organisms, which use the oxygen for their metabolism are the reason for that. If the oxygen, dissolved in water, is consumed, they can gain energy from the reduction of NO<sub>3</sub><sup>-</sup> to N<sub>2</sub> (via NO<sub>2</sub><sup>-</sup> and N<sub>2</sub>O(g)), Fe<sup>3+</sup> to Fe<sup>2+</sup> or

$\text{SO}_4^{2-}$  to  $\text{H}_2\text{S}(\text{aq})$ . The occurrence of organically bound carbon in the groundwater or in the aquifer is required for those reductions. Fig. 21 shows some microbially catalysed redox reaction dependent on  $\text{pE}/E_{\text{H}}$  conditions.

Fig. 22 schematically shows the most significant hydrogeochemical processes in aqueous systems, and at the water-solid interface.

Fig. 22 Synopsis of interaction processes in aqueous systems

## 1.2 Kinetics

For all reactions described in the previous chapter thermodynamic equilibrium, as the most stable time-independent state of a closed system, was assumed. Thermodynamic equations are incapable of describing to what extent or in which time this equilibrium is reached. Thus, slow reversible, irreversible or heterogeneous reactions actually require the consideration of kinetics, i.e. of the rate at which a reaction occurs or the equilibrium is attained.

### 1.2.1 Kinetics of various chemical processes

#### 1.2.1.1 Half-life

Fig. 23 shows the residence times  $t_R$  of waters in the hydrosphere and the half-life  $t_{1/2}$  of various reactions. If  $t_{1/2} \ll t_R$  then it can be assumed that the system is roughly in equilibrium and thermodynamic models can be used. If, on the other hand,  $t_R \ll t_{1/2}$  kinetic models must be applied.

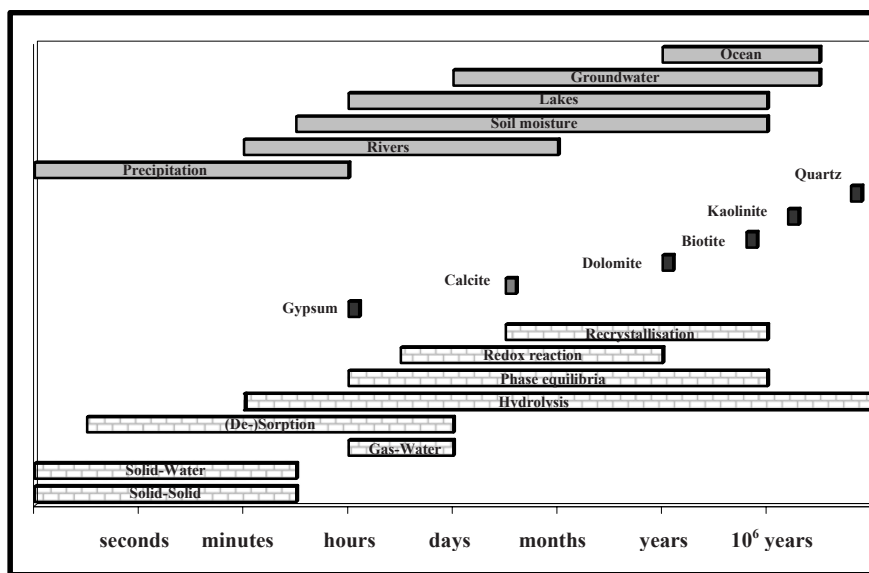

Fig. 23 Schematic comparison between the residence times  $t_R$  of waters in the hydrosphere, the dissolution of various minerals in unsaturated solutions at pH 5 and the half-life  $t_{1/2}$  of chemical processes (data after Langmuir 1997, Drever 1997)

Acid-base reactions and complexation processes especially those with low stability constants occur within micro- to milliseconds. Unspecific sorption with the formation of a disordered surface film is also a fast reaction, while the kinetics of specific sorption and mineral crystallization generally are considerably slower.

For ion exchange the reaction rate depends on the type of binding and exchange. Those processes are the fastest where the exchange only occurs at the edges of mineral grains, as e.g. with kaolinite. Incorporation of ions in mineral layers is much slower, e.g. into montmorillonite or vermiculite, or the intrusion into basal layers, as for illite. Dissolution and precipitation processes sometimes take only hours, but could also need several thousands of years. Redox reactions have long half-lives in the range of years, especially when catalysts are lacking.

### 1.2.1.2 Kinetics of mineral dissolution

For interactions between solid and liquid phases, two cases have to be distinguished: weathering of rock-forming minerals and the weathering of trace minerals.

For the weathering of rock-forming minerals, the solution kinetics is determined by the solubility-product and transport in the vicinity of the solid-water-interface. If the dissolution rate of a mineral is higher than the diffusive transport from the solid-water interface, saturation of the boundary layer and an exponential decrease with increasing distance from the boundary layer results. In the following text this kind of solution is referred to as solubility-product controlled. If the dissolution rate of the mineral is lower than diffusive transport, no saturation is attained. This process is called diffusion-controlled solution (Fig. 24 right).

**Fig. 24** Comparison between surface-controlled reactions (left; 1= interstitial sites, 2= vacant sites, 3= screw dislocation, 4= jump dislocation, 5=step dislocation) and diffusion-controlled processes (right)

In an experiment solubility-product controlled and diffusion-controlled solution can be distinguished by the fact that for diffusion-controlled solution an increase in mixing leads to an increase in the reaction rate. Since this assumption is necessarily true the other way round, it is easier to calculate if the reaction proceeds faster or slower than the molecular diffusion. If it is faster, the reaction is controlled by the solubility-product; if it is slower, it is diffusion-controlled.

For the weathering of trace minerals from the solid matrix, the dissolution occurs selectively on spots where the mineral is exposed to the surface. These mineral surfaces are usually not smooth, but show dislocations (screw, jump, step dislocations) and point defects (vacant sites, interstitial sites) (Fig. 24 left). Dissolved ions are immediately transported from the surface into solution, so that no gradient can develop. Since the total concentrations of trace minerals in the solution are low, no equilibrium can be reached. In the following this dissolution of trace minerals is called surface-controlled.

### 1.2.2 Calculation of the reaction rate

The reaction rate can be determined by inverse geochemical modeling as increase of the products or decrease of the reactants along a flow path over time. In most cases the forward reaction ( $A + B \rightarrow C$ ) and the simultaneously proceeding reverse reaction ( $C \rightarrow A + B$ ) have different reaction rates. The total kinetics is the sum of both.

$$v^+ = k^+ \prod_i (X_i)^{n_i} \quad \text{Eq. (72.)}$$

$$v^- = k^- \prod_i (X_i)^{n_i} \quad \text{Eq. (73.)}$$

$$K_{eq} = \frac{k^+}{k^-} = \prod_i (X_i)_{eq}^{n_i} \quad \text{Eq. (74.)}$$

with:

- $v^+$  = rate of the forward reaction
- $k^+$  = rate constant of the forward reaction
- $v^-$  = rate of the reverse reaction
- $k^-$  = rate constant of the reverse reaction
- $X$  = reactant or product
- $n$  = stoichiometric coefficient
- $K_{eq}$  = equilibrium constant

Table 13 shows the calculation of the reaction rate, the time law, and the half-life depending on the reaction's order. The order results from the sum of the exponents of the concentrations. The number does not necessarily have to be an integer. The half-life states in which time half of the reactants is converted into the products. Reaction rate constants  $k$  are  $10^{12}$  to  $10^{-11}$  L/s for first order reactions and  $10^{10}$  to  $10^{-11}$  L/(mol\*s) for second order reactions.

**Table 13** Calculation of reaction rate, time law, and half-life of a reaction depending on its order

	chemical reactions	reaction rate time law	half-life time
0.order reaction		$v = -K_k$ $(A) = -K_k \cdot t + (A_0)$	$t_{1/2} = \frac{(A_0)}{2 \cdot K_k}$ dependent on concentration
1.order reaction	$A \rightarrow B$ $A \rightarrow B + C$	$\frac{d(A)}{dt} = -K_k \cdot (A)$ $(A) = (A_0) \cdot e^{-K_k \cdot t}$	$t_{1/2} = \frac{1}{K_k} \cdot \ln 2$ independent on concentration
2.order reaction	$A + A \rightarrow C + D$ $A + B \rightarrow C + D$	$\frac{d(A)}{dt} = -K_k \cdot (A) \cdot (B)$ $\frac{d(A)}{dt} = -K_k \cdot (A)^2$ $\frac{1}{(A)} = -K_k \cdot t + \frac{1}{A_0}$	$t_{1/2} = \frac{1}{(A_0) \cdot K_k}$ dependent on concentration
3.order reaction	$A + B + C \rightarrow D$	$\frac{d(A)}{dt} = -K_k \cdot (A) \cdot (B) \cdot (C)$	

**1.2.2.1 Subsequent reactions**

Frequently chemical processes do not occur in one reaction but as a series of reactions.

The equilibrium constant  $k_{12}$  is derived from the principle of microscopic reversibility, i.e. in equilibrium every forward and reverse reaction has the same reaction rate.

$$K_{12} = \frac{\{D\}}{\{A\} \cdot \{B\}} = \frac{k_1 \cdot k_2}{(-k_1) \cdot (-k_2)}
 \quad \text{Eq. (76.)}$$

For subsequent reactions the total reaction rate depends on the reaction with the lowest reaction rate.

### 1.2.2.2 Parallel reactions

For reactions that run independently of each other (parallel reactions) and result in the same product, the reaction with the fastest reaction rate determines the kinetics of the whole process.

With  $k_1 > k_2 > k_3$  the reaction of Eq. 77 dominates at first. Another reaction can become predominant, when boundary conditions change during the reaction, as e.g. pH increase during calcite dissolution.

### 1.2.3 Controlling factors on the reaction rate

The reaction rate mainly depends on the concentration of reactants and products. According to the collision theory, frequent collisions and rapid conversions occur at high concentrations. Yet, not all collisions cause conversions. A certain relative position of the molecules to each other is required as well as overcoming a specific threshold energy. Besides the concentration, pH, light, temperature, organics, presence of catalysts, and surface-active trace substances can have a significant influence on reaction rates.

The empirical Arrhenius equation describes the dependency of the reaction rate on the temperature

$$\ln k = \ln A - \frac{E_a}{R} \cdot \frac{1}{T} \quad \text{Eq. (80.)}$$

with     $k$  = velocity constant  
           $A$  = empirical constant  
           $R$  = general gas constant (8.315 J/K mol)  
           $T$  = temperature  
           $E_a$  = activation energy

The activation energy is the energy required for initiating a reaction. According to transition state theory, an unstable activated complex forms, which has a fairly high potential energy from the kinetic energy of the reactants and decays within a short period of time. Its energy is converted into the binding energy respectively the kinetic energy of the product (Fig. 25). Table 14 shows typical values for the activation energy of some chemical processes.

Fig. 25 Scheme of the free energies  $\Delta G$  and formation of an activated complex  $C^*$  as a transitional state of the reaction  $A+B=AB$  (after Langmuir 1997)

Table 14 Activation energy of some chemical processes (after Langmuir 1997)

Reaction or process	range of typical $E_a$ -values [kcal/mol]
Physical adsorption	2-6
Diffusion in solution	<5
Reactions in cells and organisms	5-20
Mineral solution and precipitation	8-36
Mineral solution via surface-controlled reaction	10-20
Ion exchange	>20
Isotope exchange in solution	18 to 48
Solid phase diffusion in minerals at low temperatures	20 to 120

### 1.2.4 Empirical approaches for kinetically controlled reactions

A kinetically controlled reaction can be described by the equation:

$$\frac{m_i}{d_t} = c_{ik} \cdot k_k \quad \text{Eq. (81.)}$$

with  $m_i/dt$  = converted mass (mol) per time (s)

$c_{ik}$  = concentration of the species  $i$

$k_k$  = reaction rate (mol/kg/s)

The general kinetic reaction rate of minerals is:

$$R_K = r_K \cdot \left( \frac{A_0}{V} \right) \cdot \left( \frac{m_k}{m_{0k}} \right)^n \quad \text{Eq. (82.)}$$

with  $r_k$  = specific reaction rate (mol/m<sup>2</sup>/s)  
 $A_0$  = initial surface of the mineral (m<sup>2</sup>)  
 $V$  = mass of solution (kg water)  
 $m_{0k}$  = initial mineral mass (mol)  
 $m_k$  = mass of the mineral (mol) at a time  $t$

$(m_k/m_{0k})^n$  is a factor, which takes into account the change in  $A_0/V$  during the dissolution. For an even dissolution from surfaces and cubes  $n$  is 2/3. Frequently not all parameters are available, so that simple approaches are useful like:

$$R_K = k_K \cdot (1 - SR)^\sigma \quad \text{Eq. (83.)}$$

In Eq. 83  $k_K$  is an empirical constant and  $SR$  is the saturation rate (ion-activity product/solubility-product). Frequently the exponent  $\sigma$  equals 1. The advantage of this simple equation is that it is valid both for supersaturation and undersaturation. With saturation  $R_K$  becomes zero.  $R_K$  can also be expressed by the saturation index [ $\log(SR)$ ] (Appelo et al. 1984):

$$R_K = k_K \cdot \sigma \cdot SI \quad \text{Eq. (84.)}$$

Another example is the Monod equation, which contains a concentration-dependent term:

$$R_k = r_{\max} \left( \frac{C}{k_m + C} \right) \quad \text{Eq. (85.)}$$

with  $r_{\max}$  = maximum reaction rate  
 $k_m$  = concentration, at which the rate is 50% of the maximum rate

The Monod rate is widely used to simulate the degradation of organic matter (van Cappellen & Wang 1996). It can be derived from the general equation for first order kinetics:

$$\frac{ds_C}{dt} = -k_1 s_C \quad \text{Eq. (86.)}$$

with:  $s_C$  = organic carbon content [mol/kg soil]  
 $k_1$  = decay constant for first order kinetic reactions [1/s]

If for instance the degradation of organic carbon in an aquifer is considered, a first order degradation parameters ( $k_1 = 0.025/a$  for 0.3 mM O<sub>2</sub> and  $k_1 = 5 \cdot 10^{-4}/a$  for 3  $\mu$ M O<sub>2</sub>) can be described by the coefficients  $r_{\max} = 1.57 \cdot 10^{-9}/s$  and  $K_m = 294 \mu$ M in the Monod equation, oxygen being the limiting substance. A similar estimation

can be done for nitrate as limiting substance:  $k_1 = 5 \cdot 10^{-4}/a$  for 3 mM  $\text{NO}_3$  and  $k_1 = 1 \cdot 10^{-4}/a$  for 3  $\mu\text{M}$   $\text{NO}_3$ , which results in  $r_{\max} = 1.67 \cdot 10^{-11}/s$  and  $K_m = 155 \mu\text{M}$ . The corresponding Monod equation is as follows:

$$R_c = 6 \cdot s_c \cdot \left( \frac{s_c}{s_{c_0}} \right) \left\{ \frac{1.57 \cdot 10^{-9} m_{\text{O}_2}}{2.94 \cdot 10^{-4} + m_{\text{O}_2}} + \frac{1.67 \cdot 10^{-11} m_{\text{NO}_3^-}}{1.55 \cdot 10^{-4} + m_{\text{NO}_3^-}} \right\} \quad \text{Eq. (87.)}$$

where the factor 6 results when the concentration  $s_c$  is converted from mol/kg soil to mol/kg pore water. Plummer et al. (1978) found the following rates for the carbonate dissolution and precipitation:

$$r_{\text{Calcite}} = K_1 \cdot \{H^+\} + K_2 \{CO_2\} + K_3 \{H_2O\} - K_4 \{Ca^{2+}\} \{HCO_3^-\} \quad \text{Eq. (88.)}$$

The constants  $k_1$ ,  $k_2$  and  $k_3$  depend on the temperature and describe the forward reaction:

$$k_1 = 10^{(0.198 - 444.0 / T_K)} \quad \text{Eq. (89.)}$$

$$k_2 = 10^{(2.84 - 2177.0 / T_K)} \quad \text{Eq. (90.)}$$

if temperature  $\leq 25^\circ\text{C}$

$$k_3 = 10^{(-5.86 - 317.0 / T_K)} \quad \text{Eq. (91.)}$$

if temperature  $> 25^\circ\text{C}$

$$k_3 = 10^{(-1.1 - 1737.0 / T_K)} \quad \text{Eq. (92.)}$$

$K_4$  describes the reverse reaction and can be replaced by the term

$$1 - \left( \frac{\text{IAP}}{K_{\text{calcite}}} \right)^{\frac{2}{3}} \quad \text{Eq. (93.)}$$

where IAP is the ion-activity product and  $K_{\text{calcite}}$  is the calcite solubility-product.

## 1.3 Reactive mass transport

### 1.3.1 Introduction

In the previous chapters chemical interactions were described without considering transportation processes in aqueous systems. Models for reactive mass transport combine the chemical interactions with convective and dispersive transport, so that they can model the spatial distribution coupled to the chemical behavior. Requirement for every transport model is a flow model as accurate as possible.

### 1.3.2 Flow models

Flow models show potential or velocity fields resulting from flow in the saturated or unsaturated zone. Together with further boundary conditions, such as pore volume, dispersivity, etc., these potential fields adequately describe the flow regime in order to calculate the transport behavior (Table 15).

**Table 15 Description of homogenous, laminar transport processes of a mass  $c$  in the saturated and unsaturated zone (without dispersion and diffusion)**

	saturated zone	unsaturated zone/soil
driving force	hydraulic head (gravitational and pressure head)	matrix head (gravitational and capillary head)
model equation	DARCY $\frac{\partial c}{\partial t} = K \frac{\partial h}{\partial l} \cdot \frac{c}{\partial z}$	RICHARDS $\frac{\partial c}{\partial t} = \left( K(P_k) \frac{\partial P_m}{\partial z} \right) \cdot \frac{c}{\partial z}$
permeability $K$	constant	function of matrix head $P_m$

Under certain conditions groundwater flow in the saturated zone is more complex than described in Table 15. This is true in particular in the domain of a freshwater/saltwater-interface where the density of water has to be taken into account (density driven flow) and in case of geothermal groundwater systems where permeability (viscosity) and density of groundwater are not constant because of varying temperatures. Based on the concept of the intrinsic permeability ( $K_i$ ) even more complex systems such as multiphase flow can be described.

$$K_i = K \cdot \frac{\eta}{d \cdot g} \quad \text{Eq. (94.)}$$

with:  $K_i$  = intrinsic permeability (independent of fluid properties)  
 $K$  = permeability [m/s]  
 $\eta$  = viscosity [kg/m/s]  
 $d$  = density [kg/m<sup>3</sup>]  
 $g$  = gravity [m/s<sup>2</sup>]

### 1.3.3 Transport models

#### 1.3.3.1 Definition

The description of transport is closely related to the terms convection, diffusion, dispersion, and retardation as well as decomposition. First, it is assumed that there are no interactions between the species dissolved in water and the surrounding solid phase. Furthermore, it is assumed that water is the only fluid phase. Multiphase flow, e.g. in the systems water-air, water-organic phase (e.g. oil or DNAPL) or water-gas-organic phase, is not considered here.

Convection (also known as advection) is the vector, which results from the Darcy or the RICHARDS equations. It describes the flow velocity or the flow distance for a certain time  $t$ . In general, convection has the major influence on mass transport. Magnitude and direction of the convective transport are controlled by:

- the development of the flow field
- the distribution of the hydraulic permeability within the flow field
- the development of the groundwater table or the potentiometric surface
- the presence of sources or sinks

Concentration gradients are leveled out by diffusion by means of molecular movement. The vector of diffusion is generally much smaller than the vector of convection in groundwater. With increasing flow velocity diffusion can be neglected. In sediments, in which the  $k_f$  value is very low, and consequently the convective proportion is very small or even converging towards zero (e.g. for clay), the diffusion could become the controlling factor for mass transport.

The third term in mass transport is dispersion. The dispersion describes the mass flow, which results from velocity variations due to the geometry and the structure of the rock system. From this definition it follows that the smaller the vector of convection the smaller the effect of dispersion. The other way round, an increasing effect of dispersion occurs with higher flow velocity. Consequently, the mathematical description of the species distribution is an overlap of convection, diffusion, and dispersion.

All phenomena that cause species not to spread with the velocity of the water in soil or in groundwater are called retardation. Retardation is possible without any mass decrease. Frequently, though, retardation is combined with degradation. This “degradation” of the concentration of a species can occur by means of radioactive decay of a radionuclide or biological degradation of an organic substance. Also sorption and cation exchange can be included in this definition of “degradation”, because the considered element is entirely or partially removed from the aqueous phase.

Fig. 26 shows a simplified illustration of the described phenomena for the one-dimensional case.

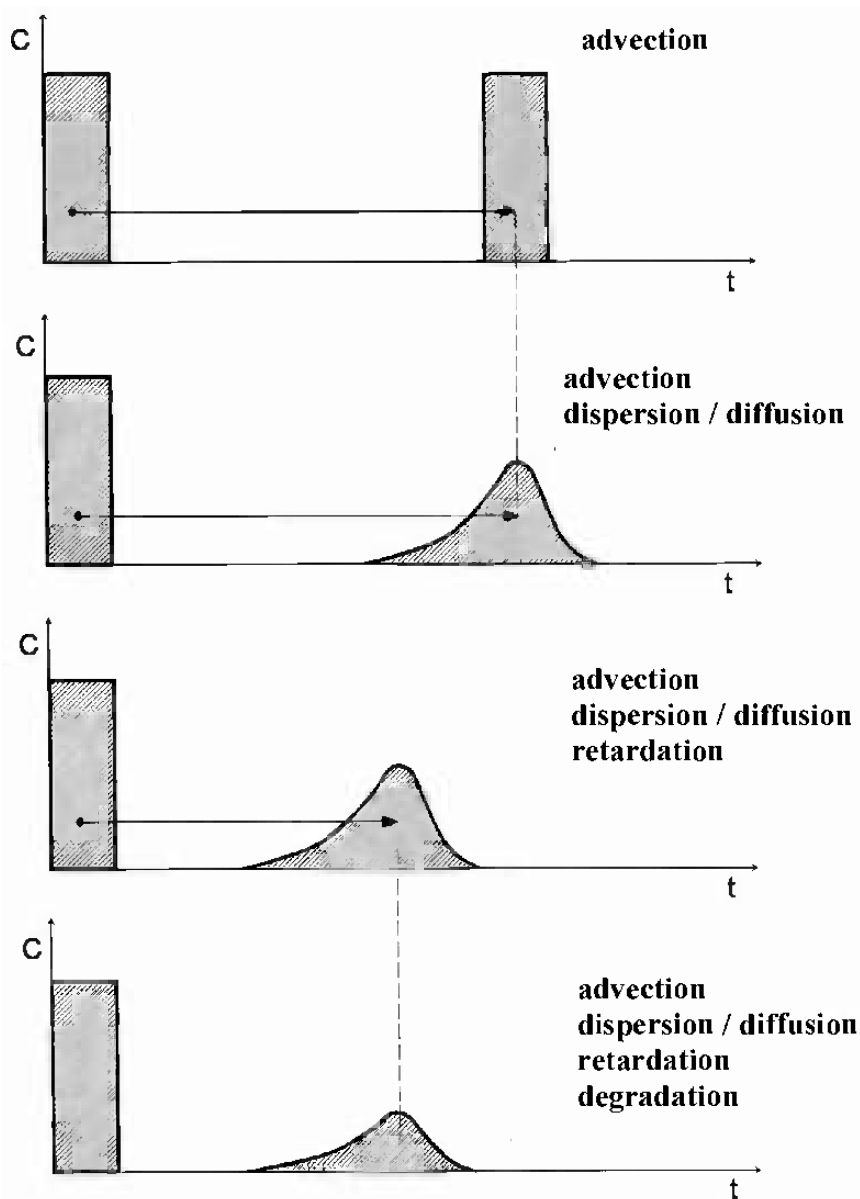

Fig. 26 Convection, dispersion/diffusion, retardation and degradation of a species (single peak input) versus time along a flow path

### 1.3.3.2 Idealized transport conditions

Within an aquifer, transport including simple chemical reactions can be described by the following equation in a one-dimensional form:

$$\frac{\partial C_i}{\partial t} = D_1 \frac{\partial^2 C_i}{\partial z^2} + D_t \frac{\partial^2 C_i}{\partial z^2} + D \frac{\partial^2 C_i}{\partial z^2} - v \frac{C_i}{\partial z} + C_{ss} \quad \text{Eq. (95.)}$$

dispersion                      diffusion                      advection                      sources/sinks

with  $C_i$  = concentration for the species  $i$  dissolved in water [mol/L]  
 $t$  = time [s]  
 $D_1$  = longitudinal dispersion coefficient [ $\text{m}^2/\text{s}$ ]  
 $D_t$  = transversal dispersion coefficient [ $\text{m}^2/\text{s}$ ]  
 $D$  = diffusion coefficient [ $\text{m}^2/\text{s}$ ]  
 $z$  = spatial coordinate [m]  
 $v$  = flow velocity [m/s]  
 $C_{ss}$  = concentration of the species (source or sink)

Simplified analytical solutions for the transport equation can be derived by analogy from basic equations of heat conduction and diffusion (e.g. Lau et al. (1959), Sauty (1980), Kinzelbach (1983), and Kinzelbach (1987)).

### 1.3.3.3 Real transport conditions

Convection, diffusion, and dispersion can only describe part of the processes occurring during transport. Only the transport of species that do not react at all with the solid, liquid, or gaseous phase (ideal tracers) can be described adequately by the simplified transport equation (Eq. 95). Tritium as well as chloride and bromide can be called ideal tracers in that sense. Their transport can be modeled by the general transport equation as long as no double-porosity aquifers are modeled. Almost all other species in water somehow react with other species or a solid phase. These reactions can be subdivided into the following groups, some of which have already been considered in the previous part of the book.

- Reactions between aqueous and gaseous phase (chapter 1.1.3)
- Dissolution and precipitation (chapter 1.1.4.1)
- Sorption and desorption of dissolved species on solid phases (chapter 1.1.4.2)
- Anion and cation exchange (chapter 1.1.4.2.2)
- Formation of colloids
- Sorption on colloids
- Homogeneous reactions within the aqueous phase (chapter 1.1.5)

All chemical reactions comprise at least two species. For models of transport processes in groundwater or in the unsaturated zone reactions are frequently simplified by a basic sorption or desorption concept. Hereby, only one species is considered and its increase or decrease is calculated using a  $K_s$  or  $K_d$  value. The

$K_d$  value allows a transformation into a retardation factor that is introduced as a correction term into the general mass transport equation (chapter 1.1.4.2.3).

As already explained in chapter 1.1.4.2.3, the  $K_d$  concept must be rejected in most cases, because of its oversimplification and its low suitability for application to natural systems. For example, modeling degradation processes only the degrading substance is considered. This concept might be suitable for radioactive decay, yet if it comes to decomposition of organic matter, it is crucial to consider decomposition products (metabolites) that form and play an important role in transport themselves.

For the saturated and the unsaturated zone, the general mass transport equation can be extended as follows, describing exchange processes with the sediment as well as interactions with the gas phase, and within the aqueous phase.

$$\frac{1}{\partial t} \partial \left( C_i + \left( S_i \frac{d}{n} \right) + \frac{G_i}{n} \right) = D_1 \frac{\partial^2 C_i}{\partial z^2} + D \frac{\partial^2 C_i}{\partial z^2} - v \frac{C_i}{\partial z} \quad \text{Eq. (96.)}$$

with  $v$  = pore velocity [m/s]

$C_i$  = concentration of the species  $i$  [mol/L]

$S_i$  = concentration of the species  $i$  on/ in the solid phase [mol/g]

$n$  = porosity

$d$  = density [g/L]

$G_i$  = concentration of the species  $i$  in the gas phase [mol/L]

$D_1$  = longitudinal dispersion coefficient [m<sup>2</sup>/s]

$D$  = diffusion coefficient [m<sup>2</sup>/s]

$z$  = spatial coordinate [m]

$t$  = time [s]

### 1.3.3.3.1. Exchange within double-porosity aquifers

Diffusive exchange between mobile and immobile water can be expressed mathematically as a mixing process between two zones: One zone containing stagnant water is coupled to a “mobile” zone, where water flows. The diffusive exchange can be described by first order kinetics.

$$\frac{\partial M_{im}}{\partial t} = \theta_{im} \cdot R_{im} \frac{\partial c_{im}}{\partial t} = \alpha (c_m - c_{im}) \quad \text{Eq. (97.)}$$

The index “m” stands for mobile and “im” for immobile.  $M_{im}$  is the number of moles of a species in the immobile zone and  $R_{im}$  the retardation factor of the immobile zone,  $c_m$  and  $c_{im}$  are the concentrations in mol/kg in the mobile and immobile zone respectively. The symbol  $\alpha$  stands for an exchange factor (1/s). The retardation factor  $R = 1 + (dq/dc)$  is determined by chemical reactions. The integrated form of Eq. 97 is:

$$c_{im} = \beta \cdot f \cdot c_{m0} + (1 - \beta \cdot f) c_{im0}$$

$$\text{with } \beta = \frac{R_m \theta_m}{R_m \theta_m + R_{im} \theta_{im}} \quad \text{Eq. (98.)}$$

$$f = 1 - \exp\left(\frac{\alpha t}{\beta \theta_{im} R_{im}}\right)$$

with  $c_{m0}$  and  $c_{im0}$  being the initial concentrations, and  $\theta_m$  and  $\theta_{im}$  the saturated porosities of the mobile and immobile zones respectively.  $R_m$  is the retardation factor of the mobile zone. From these the mixing factor  $\text{mixf}_{im}$  can be defined, which is a constant for a time  $t$ .

$$\text{mixf}_{im} = \beta \cdot f \quad \text{Eq. (99.)}$$

If this factor is implemented into Eq.98, the result is:

$$c_{im} = \text{mixf}_{im} \cdot c_{m0} + (1 - \text{mixf}_{im}) c_{im0} \quad \text{Eq. (100.)}$$

Analogously, it follows for the mobile concentration:

$$c_m = (1 - \text{mixf}_m) c_{m0} + \text{mixf}_m \cdot C_{im0} \quad \text{Eq. (101.)}$$

The exchange factor  $\alpha$  is, according to van Genuchten (1985), dependent on the geometry of the stagnant zone. For a sphere, the relation is:

$$\alpha = \frac{D_e \theta_{im}}{(a f_{s \rightarrow l})^2} \quad \text{Eq. (102.)}$$

with  $D_e$  = diffusion coefficient in the sphere ( $\text{m}^2/\text{s}$ )  
 $a$  = radius of the sphere (m)  
 $f_{s1}$  = shape factor (Table 16)

Alternatively, the problem can be solved numerically by applying a finite differences grid on the stagnant zone and determining the diffusive exchange iteratively (Parkhurst and Appelo, 1999; Appelo and Postma, 1994).

### 1.3.3.4 Numerical methods of transport modeling

The numerical methods for solving the transport equation can be subdivided into two groups:

- Solution of the transport equation including the chemical reactions (one equation system for each species to be solved)
- Coupled methods (transport model coupled with hydrogeochemical code)

For coupled models solving the transport equation can be done by means of the finite-difference method (and finite volumes) and of the finite-elements method. Algorithms based on the principle of particle tracking (or random walk), as for

instance the method of characteristics (MOC), have the advantage of not being prone to numerical dispersion (see 1.3.3.4.1).

**Table 16 Shape factors for the first order diffusive exchange between mobile and immobile water (Parkhurst & Appelo, 1999)**

Shape of stagnant region	Dimensions (x,y,z) or 2 r,z	First-order equivalent $f_{s \rightarrow 1}$	Comments

### 1.3.3.4.1. Finite-difference/finite-element method

For the finite difference method the area is discretized by rectangular cells. The distance of neighboring nodes can differ. The nodes are usually set in the center of gravity of each cell and present the average concentration of the cell. The mass transport is simulated by modeling the chemical reactions for each node in discrete time intervals. Convective, diffusive, and dispersive mass transport is calculated along the four sides of each cell, e.g. by considering the weighted means of the concentrations of neighboring cells. The ratio between convective and dispersive mass flow is called Grid-Peclet number  $P_e$  (Eq. 103).

$$P_e = \frac{|\mathbf{v}| \cdot L}{D} \quad \text{Eq. (103.)}$$

with  $D$  = dispersivity  
 $L$  = cell length

$$\text{and } |\mathbf{v}| = \sqrt{v_x^2 + v_y^2 + v_z^2} \quad \text{Eq. (104.)}$$

Both the spatial discretisation and the choice of the type of differences (e.g. uplift differences, central differences) have a strong influence on the result. This fuzziness caused by the application of different methods is summarized as “numeric dispersion”.

Numeric dispersion can be eliminated largely by a high-resolution discretisation. The Grid-Peclet number helps for the definition of the cell size. Pinder and Gray (1977) recommend the  $P_e$  to be  $\leq 2$ . The high resolution discretisation, however, leads to extremely long computing times. Additionally, the stability of the numeric finite-differences method is influenced by the discretisation of time. The Courant number (Eq. 105) is a criterion, so that the transport of a particle is calculated within at least one time interval per cell.

$$Co = \left| \mathbf{v} \frac{dt}{L} \right| < 1 \quad \text{Eq. (105.)}$$

Methods applying reverse differences in time are called implicit. Generally these implicit methods, as e.g. the Crank-Nicholson method, show high numerical stability. On the other side, there are explicit methods, and the methods of iterative solution algorithms. Besides the strong attenuation (numeric dispersion) there is another problem with the finite differences method, and that is the oscillation.

With the finite-elements method the discretisation is more flexible, although, as with the finite-differences method, numeric dispersion and oscillation effects can occur (Fig. 27).

**Fig. 27** Numeric dispersion and oscillation effects for the numeric solution of the transport equation (after Kovarik, 2000)

#### 1.3.3.4.2. Coupled methods

In physics, the random walk method has already been in use for decades to understand and model diffusion processes. Prickett et al. (1981) developed a simple model for groundwater transport to calculate the migration of contamination. An essential advantage of the methods of random walk and particle tracking is that they are free of numeric dispersion and oscillations (Abbot 1966).

For the method of characteristics (MOC), the convective term is dealt with separately from the dispersive transport term by establishing a separate coordinate system along the convection vector for solving the dispersion problem. In most modeling programs, the convection is approximated with discrete particles. A certain number of particles with defined concentrations is used and moved along the velocity field (Konikoff and Bredehoeft, 1978).

Particularly sophisticated models deal with reactive mass transport, including both the accurate description of the convective and dispersive transport of species, as well as the modeling of interactions of species in water, with solid and gaseous phases (precipitation, dissolution, ion exchange, sorption).

Coupled reactive transport modeling does the flow modeling separately as a first step. After that a modified method of characteristics (MMOC) is carried out based on the calculated flow field. The particles present a complete water analysis or a discrete water volume with certain chemical properties. These particles or water volumes are then moved for every single time step. Using a hydrochemical modeling code (e.g. PHREEQC, MINTEQA2), the interactions of the particles with their environment (i.e. rock, gaseous phases), and with each other are calculated. The results of this thermodynamic modeling are subsequently transferred back to the particles before these are “moved” one time step further. Some examples for such models are given in Table 17.

**Table 17 Selection of computer codes for reactive transport modeling**

Name	Dimen-sions	GUI	Comments
PHREEQC	1D	PHREEQC for Windows PHREEQCI	stationary flow only, dual domain mass transfer
EQ6	1D	No	stationary flow only
TREAC	2D	Yes, integrated	flowpath coupled with PHREEQC
PHAST	2D/3D	GoPHAST WPHAST	modified version of HST3D (restricted to constant fluid density and constant temperature) coupled with PHREEQC
MINTRAN	2D	No	finite element transport module (PLUME2D), coupled with MINTEQA2
Crunch	2D(3D)	No	density driven flow, Monod-Type-Reactions, EQ3/6-data
TOUGH-REACT	2D/3D	PetraSim	chemically reactive non-isothermal flows of multiphase fluids in porous and fractured media (geothermal systems, CO <sub>2</sub> sequestration, nuclear repositories)

Software like SEAM3D, a modified version of MT3DMS which is based on Modflow, can handle a set of constituents, however, only by means of the  $K_d$  concept. Therefore real world problems can not be modeled by this approach and it is not a reactive transport code.

An extremely simplified application of the described approach is already implemented in the PHREEQC program. Reactive mass transport can be modeled for the one-dimensional case at constant flow rates considering diffusion and dispersion.

Taking into consideration a high possible number of chemical reactions for the reactive mass transport, like what is done for coupled models, the computing times mainly result from the calculations within the thermodynamic code. The 2D or 3D models easily lead to unreasonably long computing times. Since information on the chemical heterogeneity of an aquifer is frequently lacking, the calculation of a 1D model is generally preferable.

However, there is a severe disadvantage with one-dimensional models: they do not take into account the dilution due to the transversal dispersion. Consequently a mass  $m$ , that is not susceptible to any chemical reaction, occurs “blurred” at a point  $x$  downstream from  $x_0$  (the location of  $m$  input) due to longitudinal dispersion. The dispersion leads to a smaller maximum concentration, however, and the mass integral equals the mass added at  $x_0$ . Thus, the impulse of mass remains constant along any simulated one-dimensional distance.

In reality, however, transversal dispersion  $D_t$  causes mass exchange in  $y$  and  $z$  direction leading to dilution. This dilution is a function of  $D_t$  and the flow velocity  $v$ . If  $D_t$  and  $v$  are constant within the flow field, than the resulting dilution can be described by a linear function or a constant factor, respectively. The value for this factor can be determined using a conservative 3D model taking into account the

aquifer thickness in particular. If, for instance in a conservative tracer model the contaminant concentration decreases by 50 percent along a certain distance through dispersion, it follows that, using a 1D model of reactive mass transport, half of the water within the column has to be substituted by uncontaminated groundwater.

## 2 Hydrogeochemical Modeling Programs

### 2.1 General

A selection of computer programs available is listed in Fig. 28 in chronological order. The first generation of geochemical computer programs was developed and published in the beginnings of the 1970's. New programs appeared at the end of the 1970's with improved features. From the early 1980's on it became possible to install these programs on personal computers while mainframes had been the computer platforms until then.

The most frequently used models are MINTEQA2 (Allison et al. 1991), WATEQ4F (Ball & Nordstrom 1991), PHREEQC (PHREEQE) (Parkhurst & Appelo 1999, Parkhurst 1995 & Parkhurst et al. 1980) and EQ 3/6 (Wolery 1992a and 1992b).

#### 2.1.1 Geochemical algorithms

The most common approach used by geochemical modeling codes to describe the water-gas-rock-interaction in aquatic systems is the ion-association theory outlined briefly in chapter 1.1.2.6.1. However, reliable results can only be expected up to ionic strengths between 0.5 and 1 mol/L. If the ionic strength exceeds this limit, the ion-interaction theory (e.g. PITZER equations, chapter 1.1.2.6.2) may solve the problem and computer codes have to be based on this theory. The species distribution can be calculated from thermodynamic databases using two different approaches (chapter 2.1.4):

- Determination of the thermodynamically most stable state by minimization of the free energies of reaction (lowest energy state) (e.g. CHEMSAGE) (chapter 2.1.2)
- Solving the non-linear set of equations resulting from equilibrium constants and mass balances in the system (e.g. PHREEQC, EQ 3/6, WATEQ4F, MINTEQA2 etc.) (chapter 2.1.3)

Both processes presuppose the establishment of chemical equilibrium and mass balance. Being in equilibrium, the relation between the equilibrium constant  $K$  and the free energy is defined as (see also chapter 1.1.2.2):

$$G_0 = -R \cdot T \cdot \ln K \quad \text{Eq.(106.)}$$

$$\text{or for } T = 25 \text{ }^{\circ}\text{C: } G_0 = -5.707 \cdot \log K \quad \text{Eq.(107.)}$$

Fig. 28 Overview on hydro-geochemical modeling programs in chronological order

Table 18 gives an example for the calculation of an equilibrium constant from the free energy. Due to the relatively big error for the determination of the free energy, it is not advisable to perform such conversions unless unavoidable. Direct experimental determination of equilibrium constants is often more reliable.

**Table 18** Example for the calculation of an equilibrium constant using the standard-free energy.

Species	G [K·J/mol]
Calcite	-1130.61
Ca <sup>2+</sup>	-553.54
CO <sub>3</sub> <sup>2-</sup>	-527.90
$-G = G_{\text{Calcite}} - G_{\text{Ca}} - G_{\text{CO}_3}$ $-G = -1130.61 - (-553.54) - (-527.90)$ $-G = -49.17$ $\log K_{\text{Calcite}} = -49.17/5.707 = -8.6157$	
for comparison log K from the experiments (Plummer & Busenberg 1982) $\log K_{\text{Calcite}} = -8.48 \pm 0.02$	

If the solubility constant for a certain reaction is not explicitly given in a database, but the solubility constants of partial reactions are known, the solubility constant of the total reaction can be calculated from the solubility constants of the partial reactions (see Table 19).

**Table 19** Example for the calculation of the equilibrium constant of a reaction using the equilibrium constants of partial reactions

no equilibrium constant available for the following reaction: $\text{CaCO}_3 + \text{CO}_2 + \text{H}_2\text{O} = \text{Ca}^{2+} + 2\text{HCO}_3^-$	
$\text{CaCO}_3 = \text{Ca}^{2+} + \text{CO}_3^{2-}$	$\log K = -8.48$
$\text{CO}_2 + \text{H}_2\text{O} = \text{H}_2\text{CO}_3$	$\log K = -1.47$
$\text{H}_2\text{CO}_3 = \text{H}^+ + \text{HCO}_3^-$	$\log K = -6.35$
$\text{H}^+ + \text{CO}_3^{2-} = \text{HCO}_3^-$	$\log K = +10.33$
sum of single reactions: $\text{CaCO}_3 + \text{CO}_2 + \text{H}_2\text{O} + \text{H}_2\text{CO}_3 + \text{H}^+ + \text{CO}_3^{2-}$ $= \text{Ca}^{2+} + \text{CO}_3^{2-} + \text{H}_2\text{CO}_3 + \text{H}^+ + \text{HCO}_3^- + \text{HCO}_3^-$ equals: $\text{CaCO}_3 + \text{CO}_2 + \text{H}_2\text{O} = \text{Ca}^{2+} + 2\text{HCO}_3^-$  Sum of logKs = $-8.48 + (-1.47) + (-6.35) + 10.33 = -5.97$ (calculated log K for total reaction)	

Using programs where the source code is not available, as e.g. CHEMSAGE, offers no means for individual and independent control. Such programs are not advisable for scientific work and risk assessment studies (e.g. high radioactive waste repositories).

### 2.1.2 Programs based on minimizing free energy

CHEMSAGE (ESM (Engineering and Materials Science) Software, <http://www.esm-software.com/chemsage/>) is a program family based on the minimization of the Gibbs' energy and distributed commercially.

As successor of SOLGASMIX (Besmann 1977), CHEMSAGE is mainly used for technical issues, e.g. development of alloys, ceramics, semiconductors, and superconductors, material processing, and investigation of material behavior.

Dynamic reactions like processes in blast furnaces, roasting processes, or the solidification of liquid alloys can be simulated using the REACTOR MODEL MODULE. Raw material and energy are input parameters with which reactions in the gaseous and condensed phases are simulated under different boundary conditions as well as with different fluxes of material in different parts of the reactor.

According to the distributor, it is also possible to address geochemical problems, environmental pollution in soil, air, and water, and impact of toxic, non-toxic and radioactive waste disposals with the implementation of several modules from the program SUPCRT 92 (Johnson et al. 1992).

However, only few applications in aquatic systems were found in literature. A reason for the rare use in the areas of hydrogeology and environmental science may also be the commercial marketing of both the program and the accompanying databases.

### **2.1.3 Programs based on equilibrium constants**

Computer codes used commonly by geo-scientists and environmental engineers are based on equilibrium constants. Frequently used programs are WATEQ4F, MINTEQA2, EQ 3/6, and PHREEQC. Data processing is very convenient in WATEQ4F using standard Excel files, however, limited to calculations of analytical error, speciation and saturation index (<http://water.usgs.gov/software/wateq4f.html>). Using MINTEQA2, it is additionally possible to calculate the distribution of dissolved and adsorbed species (on solid phases) ([http://www.scisoftware.com/products/minteqa2\\_overview/minteqa2\\_overview.html](http://www.scisoftware.com/products/minteqa2_overview/minteqa2_overview.html)). The application spectrum of PHREEQC and EQ 3/6 is far greater. Therefore, these two programs are described in more detail. While PHREEQC is public domain software ([http://wwwbrr.cr.usgs.gov/projects/GWC\\_coupled/phreeqc/](http://wwwbrr.cr.usgs.gov/projects/GWC_coupled/phreeqc/)), EQ 3/6 has to be purchased at the Lawrence Livermore National Laboratories (<https://ipo.llnl.gov/technology/software/softwaretitles/eq36.php>).

#### **2.1.3.1 PHREEQC**

The program PHREEQC dates back to 1980 (Parkhurst et al. 1980), at that time written in FORTRAN and named PHREEQE. The option of the program comprised:

- mixing of waters
- modeling equilibrium between solid and aqueous phase by dissolution-precipitation reactions
- modeling effects of changes in temperature

- calculation of element concentrations, molalities, activities of aquatic species, pH, pE, saturation index, mole transfer as function of reversible/irreversible reactions

In 1988, a version of PHREEQE was written including PITZER equations for ionic strengths greater 1 mol/L thus applicable for brines or highly concentrated electrolytic solutions (PHRQPITZ, Plummer et al. 1988). PHREEQM (Appelo & Postma 1994) included all options of PHREEQE and additionally a one-dimensional transport module taking into account dispersion and diffusion. PHRKIN was an add-on module to PHREEQE to model kinetically controlled reactions.

In 1995 PHREEQC (Parkhurst 1995) was completely rewritten using the C programming language. This version removed nearly all limits regarding number of elements, aquatic species, solutions, phases, exchangers and surface complexes by abandoning FORTRAN formats in the input files. Additionally, the equation solver was revised (more robust now) and several other options were added. With the 1995 version to the present, the following options have been possible:

- to enter the measured concentration of an element in different master species in the input data (e.g. N as  $\text{NO}_3$ ,  $\text{NO}_2$  and  $\text{NH}_4$ )
- to define the redox potential either by the measured  $E_H$  value (as pE value) or via a redox couple [e.g. As(III)/As(V) or U(IV)/U(VI)]
- to model surface-controlled reactions such as surface complexation and ion exchange by integrated double-layer models (Dzombak & Morel 1990) and a non-electrostatic model (Davis & Kent 1990)
- to model reactions with multicomponent gas phases as closed or open systems
- to administer the amounts of minerals in the solid phase and to determine automatically thermodynamically stable mineral associations
- to calculate the amount of water and the pE value in the aquatic phase during reaction and transport calculations using hydrogen-oxygen-mole equilibria and thus to model the water consumption or water production correctly
- to model convective mass transport with a one-dimensional transport module
- to model the composition of a given water by inverse modeling based on one, or several initial waters and chemical changes that occur along a flowpath

The most recent version, PHREEQC in the version 2 (Parkhurst & Appelo 1999), additionally allows for the following simulations:

- the formation of ideal and non-ideal solid solution minerals
- kinetic reactions with user-defined conversion rate
- dispersion and/or diffusion in 1D transport and adding immobile cells as option to the mobile cells in a 1D column
- change the number of exchanger places with dissolution or precipitation of reactants
- Inclusion of isotope balances in inverse modeling

Furthermore, it is possible to shorten the data output user-defined and to export it in a spreadsheet compatible data format. A BASIC interpreter program is implemented for programming user-specific questions concerning kinetics and output formats. The BASIC interpreter also supports direct graphic output in connection with the user interface "PHREEQC for Windows". Several revised versions were made available since 1999 and updates are still ongoing.

Two features that a user might still miss in the latest PHREEQC Version 2.14.3 (with the Windows Interface 2.14.02, release November, 17, 2007) are:

- consideration of uncertainties for thermodynamic constants
- inverse modeling for parameter fitting, such as e.g. pK values

As an add-on to PHREEQC, the program LJUNGSKILE (Odegaard-Jensen et al. 2004, <http://www.geo.tu-freiberg.de/software/Ljungskile/index.htm>) is introduced in section 2.2.2.1.4 to consider uncertainties in model input parameters. Independent programs like FITEQL4 (Herbelin and Westall 1999) or Protonfit (Turner and Fein 2006) can be used if questions of parameter fit have to be addressed. Another program which is also based on PhreeqC and overcomes PHREEQC's limitations of one-dimensional steady-state flow with simple boundary conditions only, is PHAST (see section 2.2.2.5.3 for an example).

### 2.1.3.2 EQ 3/6

EQ 3/6 consists of two programs: EQ 3 is a pure speciation code whose results are processed for further questions within EQ 6. In the early 1980s and 1990s, EQ3/6 was the leading geochemical software code since it already contained features like solid-solution minerals, surface complexation, kinetically controlled reactions, ion-association and ion-interaction (Pitzer) and an extended temperature range from 0 to 300°C which were widely missing in other programs including PHREEQC. However during the last couple of years there was no further substantial development within EQ3/6 while all the above mentioned features were successively covered by the most recent versions of PHREEQC.

A major disadvantage today is that EQ 3/6 remained written in FORTRAN and that there is no graphical user interface. All EQ 3/6 input files and thermodynamic constants have to be written in FORTRAN format which makes handling prone to errors. Errors in the format (placement within a row) can easily lead to fatal errors. Thermodynamic data and input definition for PHREEQC is much easier since reaction equations are written in the syntax of chemical formulas. A comparison of Fig. 29 and Fig. 30 shows how complicated the definition of the same mineral phase (rutherfordine,  $\text{UO}_2\text{CO}_3$ ) is in EQ 3/6 compared to PHREEQC.

Rutherfordine	606
UO2CO3 = UO2+2 + CO3-2	
log_k	-14.450
delta_h	-1.440 kcal

**Fig. 29** Definition of the mineral rutherfordine in PHREEQC (WATEQ4F.dat)

```
UO2CO3
  date last revised = 02-jul-1993
  keys = solid

mation
```

**Fig. 30** Excerpt from the NEA database for EQ 3/6; definition of the mineral rutherfordine (elements which exist in a similar form in the PHREEQC database are **boldly** marked; the different log\_k values are due to different reaction equations (also compare to chapter 2.1.5))

Similarly, an input file looks much more simple in PHREEQC than in EQ 3/6 as shown in Fig. 31 and Fig. 32 for the dissolution of the mineral rutherfordine in water with 1 mmol/L sodium-chloride and low sulfate concentrations (0.0001 mmol/L) under oxidizing conditions (pE = 14) at 25 °C and a CO<sub>2</sub> partial pressure of 0.033 kPa (atmospheric conditions).

```

Rutherfordine      0

END
```

**Fig. 31** Example for a PHREEQC input file (dissolution of the mineral rutherfordine as a function of the CO<sub>2</sub> partial pressure)

Since there are no more advanced options in EQ3/6 compared to the latest version of PHREEQC, the simplicity of input and thermodynamic constant definition strongly votes for the use of PHREEQC which is furthermore public domain including the graphical user interface. PHREEQC will also be used in the present

textbook for the modeling the exercises in chapter 3. The utilization of PHREEQC is explained in greater detail in chapter 2.2.

## 2.1.4 Thermodynamic databases

### 2.1.4.1 General

Thermodynamic databases are the primary source of information of all geochemical modeling programs. Basically, it is possible to create individual thermodynamic databases with almost any program. However, it is a considerable effort and requires great care. Normally one accesses already existing databases.

Table 20 shows a variety of thermodynamic data collections and the elements considered. The thermodynamic data are usually not available in a current

database format but in a form which is needed for the specific program. To use thermodynamic data, e.g. in PHREEQC, they have to be converted into the respective format using a transfer program.

With the help of appropriate filters it is also possible to create a partial database out of the standard database. Especially when a huge number of analyses have to be calculated - as with a coupled modeling (transport plus reaction) - CPU-time can be saved with a reduced database. However, it must be verified that the partial database yields comparable results to the original database.

**Table 20 Thermodynamic databases with elements considered**

<sup>1</sup> additionally considered in WATEQ4F.dat: fulvate and humate

<sup>2</sup> additionally considered in MINTEQ.dat: 2-, 3-, 4-methylpyridine, acetate, benzoate, butanoate, citrate, cyanate, cyanide, diethylamine, dimethylamine, EDTA, ethylene, ethylenediamine, formate, glutamate, glycine, hexylamine, isobutyrate, isophthalate, isopropylamine, isovalerate, methylamine, n-butylamine, n-propylamine, NTA, para-acetate, phthalate, propanoate, salicylate, tartrate, tributylphosphate, trimethylamine, trimethylpyridine, valerate

additionally considered in MINTEQ v4.dat: Co, Mo, acetate, benzoate, butylamine, butyrate, citrate, cyanide, diethylamine, dimethylamine, dom\_a, dom\_b, dom\_c, edta, ethylenediamine, formate, 4-picoline, glutamate, glycine, hexylamine, isobutyrate, isophthalate, isopropylamine, isovalerate, methylamine, nta, phenylacetate, phthalate, propionate, propylamine, salicylate, tartarate, 3-picoline, trimethylamine, 2-picoline

<sup>3</sup> additionally considered in LLNL.dat: acetate, ethylene, orthophthalate

#### 2.1.4.2 Structure of thermodynamic databases

A thermodynamic geochemical database is divided into several blocks with different variables. If it is defined as relational database, several tables (relations) with different variables are necessary. However, many programs (among them PHREEQC and EQ 3/6) read the data from a plain ASCII file that is separated in

logical blocks by keywords. Each logical block has a different syntax for reading and interpreting data. In PHREEQC, there are the following blocks:

- master species in solution (Table 21) (SOLUTION\_MASTER\_SPECIES)
- species in solution (Table 22) (SOLUTION\_SPECIES)
- phases: solid phases and gas phases (PHASES)
- exchange of master species (EXCHANGE\_MASTER\_SPECIES)
- exchange of species (EXCHANGE\_SPECIES)
- surface master species (SURFACE\_MASTER\_SPECIES)
- surface species (strong and week binding species, sorted by cations and anions) (SURFACE\_SPECIES)
- reaction rates (RATES)
- END

**Table 21 Example for the definition of master species in solution (SOLUTION\_MASTER\_SPECIES) from the PHREEQC database WATEQ4F.dat**

Element	Master species	Alkalinity	mole mass in g/mol	atomic mass of elements
C	CO3-2	2.0	61.0173	12.0111
H	H+	-1.0	1.008	1.008
Fe(+2)	Fe+2	0.0	55.847	
Fe(+3)	Fe+3	-2.0	55.847	
N	NO3-	0.0	14.0067	14.0067
N(-3)	NH4+	0.0	14.0067	
N(0)	N2	0.0	14.0067	
N(+3)	NO2-	0.0	14.0067	
N(+5)	NO3-	0.0	14.0067	
P	PO4-3	2.0	30.9738	30.9738
S(-2)	H2S	0.0	32.064	
S	SO4-2	0.0	96.0616	32.064
Si	H4SiO4	0.0	60.0843	28.0843

The contribution of each master species to the alkalinity in Table 21 is calculated according to the predominant species at a pH of 4.5. For example, the predominant species for  $\text{Fe}^{3+}$  at pH 4.5 is  $\text{Fe}(\text{OH})_2^+$  with two  $\text{OH}^-$ -ions that are able to bind two  $\text{H}^+$ -ions. Therefore a factor of -2 results for the alkalinity. For inorganic C with the dominant species  $\text{H}_2\text{CO}_3$  and two  $\text{H}^+$ -ions the factor will be +2.

Column 4 in Table 21 specifies in which way the input in mg/L has to be done. In this example, C has to be defined as carbonate, however, nitrate, nitrite, ammonia each defined as elementary nitrogen, P as elementary phosphorous, S as sulfate and Si as  $\text{SiO}_2$ . If, for example, P is defined as phosphate in mg/L, all subsequent calculations would be wrong. A thorough study of the respective databases is thus absolutely necessary for each input. These problems can be avoided by entering all concentrations in mol/L.

For all reactions added manually to existing databases, a master species - if not yet existent - has to be defined using the keyword `SOLUTION_MASTER_SPECIES`.

For the species in solution (`SOLUTION_SPECIES`, Table 22), listed in the top row with current number, solubility constant  $\log k$  and enthalpy  $\Delta h$  are given in kcal/mol or kJ/mol at a temperature of 25 °C. Following the sub-keyword “gamma”, parameters for the calculation of the activity coefficient  $\gamma$  according to the WATEQ-DEBYE-HÜCKEL ion-association theory (compare to chapter 1.1.2.6.1) are given. With the sub-keyword “analytical”, coefficients  $A_1$  to  $A_5$  are defined to calculate the temperature dependency of the solubility-product.

**Table 22** Example of definition of species in solution (`SOLUTION_SPECIES`) from `WATEQ4F.dat`

CO3-2 primary master species					
CO3-2 = CO3-2					
log_k	0.0				
-gamma	5.4	0.0			
CaCO3 78					
Ca+2 + CO3-2 = CaCO3					
log_k	3.224				
delta_h	3.545 kcal				
-analytical	-1228.732	-0.299444	35512.75	485.818	0.0
S2-2 502					
HS- = S2-2 + H+					
log_k	-14.528				
delta_h	11.4kcal				
-no_check					
-mole_balance	S(-2)2				
-gamma	6.5	0.0			

“No check” indicates that the reaction equation is not checked for charge and elemental balance (by default all reactions are checked). If “no check” is used, “mole balance” is required to define the stoichiometry of the species, e.g. for polysulfide species (see Table 22,  $S_2^{2-}$  contains 2 S atoms, but only one will be used for the combination of  $HS^-$ ).

Definitions of reactions with solid or gaseous phases (PHASES) are done accordingly to those of dissolved species. When looking up equilibrium constants in a database it is important to look under the correct keywords. The equilibrium constant of the reaction  $CaCO_3 = Ca^{2+} + CO_3^{2-}$  describing the dissolution of the mineral calcite ( $\log K = -8.48$ , under the keyword PHASES) is totally different from the equilibrium constant of the reaction  $Ca^{2+} + CO_3^{2-} = CaCO_3^0$  describing the formation of the aquatic complex  $CaCO_3^0$  ( $\log K = 3.224$ , under the keyword `SOLUTION_SPECIES`) even though the reactions may look alike at first glance.

`EXCHANGE_MASTER_SPECIES` defines the interrelation between the name of an exchanger and its master species. Based on this, `EXCHANGE SPECIES` describes a half-reaction and requires a selectivity coefficient for each exchanger species. In contrast to stability constants or dissociation constants, these selectivity

coefficients are critical data since they depend not only on the aqueous phase but on the respective solid phase with the specific features of its inner and outer surfaces (see also chapter 1.1.4.2). Therefore, within thermodynamic databases selectivity coefficients are only to be seen as functors that have to be replaced by measured data according to site-specific exchange constants.

SURFACE\_MASTER\_SPECIES defines analogously the interrelation between the name of surface binding sites and the surface master species, whereas SURFACE\_SPECIES describes reactions for any surface species sorted by cations and anions as well as by strongly and weakly bound partners.

Following the keyword RATES, reactions rates and mathematical equations are listed from different references to describe the kinetics of K-feldspar, albite, calcite, pyrite, organic carbon, and pyrolusite reactions. The predefined rates only serve as examples and must be replaced or adjusted by site-specific data, e.g. in the case of organic decay.

### 2.1.5 Problems and sources of error in geochemical modeling

Hydrochemical analyses should be as complete and correct as possible because they are the basic prerequisite of a reliable hydrogeochemical model. Errors in the initial hydrochemical analyses propagate through all simulations to the final result. Fig. 33 to Fig. 35 show the calculation of saturation indices for calcite and dolomite as well as the calculation of the CO<sub>2</sub> partial pressure omitting different variable from the following analysis to simulate input of an incomplete analysis:

pH = 7.4, temp. = 8.1°C, conductivity = 418 µS/cm, concentrations in mg/L

Ca <sup>2+</sup>	74.85	Cl <sup>-</sup>	2.18	Fe <sup>2+</sup>	0.042	Mn <sup>2+</sup>	0.014
Mg <sup>2+</sup>	13.1	HCO <sub>3</sub> <sup>-</sup>	295.0	Pb <sup>2+</sup>	0.0028	Zn <sup>2+</sup>	0.379
Na <sup>+</sup>	1.88	SO <sub>4</sub> <sup>2-</sup>	2.89	Cd <sup>2+</sup>	0.0026	SiO <sub>2</sub>	0.026
K <sup>+</sup>	2.92	NO <sub>3</sub> <sup>-</sup>	3.87	Cu <sup>2+</sup>	0.030	DOC	8.8255

Generalizing assumptions made in hydrogeochemical modeling programs complicate the transferability to natural systems, e.g. assuming thermodynamic equilibrium. This assumption is often not true especially for redox reactions being dominated by kinetics and catalyzed by microorganisms, or for precipitation of certain minerals. Both processes can maintain disequilibria over a long time.

Numerical dispersion or oscillation effects can occur as accidental source of error when using finite differences and finite element methods while modeling mass transport. Utilizing the criteria of numerical stability (Grid-Peclet number or Courant number) or the random walk procedure, these errors can be either reduced or even eliminated.

**Fig. 33** CO<sub>2</sub> equilibrium partial pressure of complete and incomplete water analyses (calculated with PHREEQC after data by Merkel 1992)

**Fig. 34** Calcite saturation index of complete and incomplete water analyses (calculated with PHREEQC after data by Merkel 1992)

**Fig. 35 Dolomite saturation index of complete and incomplete water analyses (calculated with PHREEQC after data by Merkel 1992)**

However, the most common sources of divergent results are both the approach used for the calculation of the activity coefficient (chapter 1.1.2.6) and the thermodynamic databases (chapter 2.1.4). The thermodynamic databases provide the respective program with the fundamental geochemical information for individual species. Different databases use - sometimes significantly - differing data with different solubility-products, different species, minerals and reaction equations. Nordstrom et al (1979, 1990), Nordstrom & Munoz (1994), Nordstrom (1996, 2004) discuss this inconsistency of thermodynamic databases in detail. For some species for which stability constants have been published not even the existence of the respective species has been proved beyond doubt, as can be shown in the following example.

Two surveys regarding uranium species in the year 1992 (Grenthe et al. 1992 [NEA 92] and Fuger et al. 1992 [IAEA 92]) came up with quite different interpretations regarding some hexavalent uranium-hydroxo-species. These differences have considerable influence on the species distribution of a measured total uranium concentration at neutral and basic pH values (Table 23).

Even greater differences exist for the mineral barium arsenate  $\text{Ba}_3(\text{AsO}_4)_2$ . While this mineral is not contained in PHREEQC.dat and LLNL.dat, it is listed in MINTEQA2.dat as well as in WATEQ4F.dat with such a low solubility-product, that this mineral may react as arsenic-limiting phase during thermodynamic modeling. However, it is not  $\text{Ba}_3(\text{AsO}_4)_2$  but  $\text{BaHAsO}_4 \cdot \text{H}_2\text{O}$  that might be a limiting mineral phase under certain conditions (Planer-Friedrich et al. 2001). The quoted low solubility-product for  $\text{Ba}_3(\text{AsO}_4)_2$  is based on a misinterpretation of the precipitating mineral (Chukhlantsev 1956). However, even though this misinterpretation has been clarified already in 1985 (Robins 1985), the constant

has never been changed in the above cited thermodynamic databases (Zhu & Merkel 2001).

**Table 23 Dissociation constants for U (6) hydroxo species (\*\* = no data available)**

Species	log K NEA (1992)	log K IAEA (1992)
$\text{UO}_2\text{OH}^+$	-5.2	-5.76
$\text{UO}_2(\text{OH})_2^0$	< -10.3	-13
$(\text{UO}_2)_2(\text{OH})_2^{2+}$	-5.62	-5.54
$(\text{UO}_2)_3(\text{OH})_5^+$	-15.55	-15.44
$(\text{UO}_2)_3(\text{OH})_2^+$	-11.9	***
$(\text{UO}_2)_2(\text{OH})_3^+$	-2.7	-4.06
$(\text{UO}_2)_4(\text{OH})_7^+$	-21.9	***
$\text{UO}_2(\text{OH})_3^-$	-19.2	***
$(\text{UO}_2)_3(\text{OH})_7^-$	-31	***
$\text{UO}_2(\text{OH})_4^{2-}$	-33	***

Furthermore, it is of great importance that solubility-products and complexation constants taken from the literature are clearly attached to the appropriate reaction equation. The example of the definition of the mineral rutherfordine ( $\text{UO}_2\text{CO}_3$ ) in PHREEQC (Fig. 29) and EQ 3/6 (Fig. 30) shows that different reaction equations can be used for the same mineral. Whereas PHREEQC uses the chemical equation  $\text{UO}_2\text{CO}_3 = \text{UO}_2^{2+} + \text{CO}_3^{2-}$ , EQ 3/6 applies the equation  $\text{UO}_2\text{CO}_3 + \text{H}^+ = \text{HCO}_3^- + \text{UO}_2^{2+}$ . Because of the different reaction equations, the solubility-product will not be identical.

Additionally, thermodynamic data are established by laboratory tests under defined boundary conditions (temperature, ionic strength) that can be transferred to natural, geogenic conditions only to a limited extent. Uranium thermodynamic databases were e.g. mainly derived from nuclear research dealing with relatively high uranium concentrations of up to 0.1 mol/L in matrices with a total mineralization of up to 1 mol/L whereas concentrations in natural aquatic systems are normally in the nmol/L for uranium and mmol/L for total mineralisation.

In the laboratory, often relatively high ionic strengths (0.1 or 1 molar solution) have to be used, e.g. when working under extreme pH conditions. To refer complexation constants or solubility-products back to an ionic strength of zero, the same procedures as for the calculation of the activities from measured concentrations can be applied (e.g. extended DEBYE-HÜCKEL limiting-law equation). However, because the validity of the ion-association theory ends with 1 molar solutions, such experiments are in a range that is no longer valid with the ion-association theory. If solubility-products and complexation constants are extracted from literature, data will be gathered that has been obtained under different experimental boundary conditions, and processed by different calculation procedures considering the extrapolation of constants to an ionic strength of zero. Sometimes these data are not even recalculated to an ionic strength of zero at all.

Progress toward an internally consistent and reliable thermodynamic database for geochemical calculations is a tedious, slow, and poorly supported enterprise. For some applications, a smaller but consistent subset of data is sufficient. If

aqueous species were determined analytically, their concentrations can be compared to modeled values from total element concentrations to estimate the reliability of the modeling.

It is also important to indicate the range of the error of each species for calculated species distributions. The pH value is a significant parameter to be measured. In practice, it can be measured with an accuracy of  $\pm 0.1$  pH units. Particularly with respect to reactions in which several protons occur, this uncertainty may have a significant impact on the result (Fig. 36). Sensitivity analyses can be performed by simply entering the anticipated error in the analytical data (such as a  $\pm 0.1$  pH change) and propagating this change through a speciation and saturation index calculation. This type of error propagation can demonstrate the effect of errors from analytical data on geochemical calculations. The program code LJUNGSKILE offers the possibility to include uncertainty analysis in PHREEQC (see section 2.2.2.1.4 for an example).

Fig. 36 Uranyl species in relation to the measured pH value; solid lines are the modeled relative amounts of uranyl species, dashed lines represent an upper and lower range of uncertainty for each modeled species (after Meinrath 1997)

## 2.2 Use of PHREEQC

### 2.2.1 The structure of PHREEQC and its graphical user interfaces

A geochemical model consists of several components:

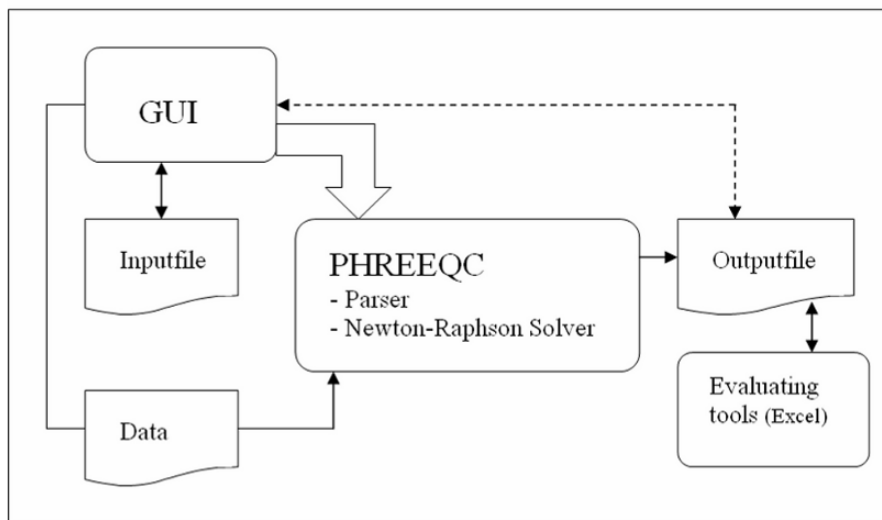

- the input file describing the problem to be solved

- the geochemical database
- the parser reading the input file and deriving a series of equations from it
- the solver for a series of resulting nonlinear functions (Newton-Raphson)
- the output file containing the results
- and optional graphical or tabular presentations of results

PHREEQC is the core of the geochemical model containing the parser and the solver. The parser extracts species information from the input file and links it based on the equations in the database in nonlinear reaction equations. These species equations are then substituted by mole- and charge-balance equations. The goal is to reach equilibrium, where all functions relevant to a specific equilibrium calculation are equal to zero. The Newton-Raphson approach is used to find the zeros of the functions by which each function is differentiated with respect to each master unknown to form the Jacobian matrix. A set of linear equations is formed from the Jacobian matrix that can be solved to approximate iteratively a solution to the nonlinear equations.

The input files must be written in certain syntax and two graphical user interfaces (GUI) are available to support the writing of the input file:

- PHREEQC for Windows
- PHREEQCI

**Fig. 37 Schematic chart of geochemical modeling with PHREEQC. GUI's can be either PHREEQC for Windows or PHREEQCI. Installing one the GUI's will automatically install PHREEQC and several databases**

Both GUI's are public domain and can be downloaded via [http://wwwbrr.cr.usgs.gov/projects/GWC\\_coupled/phreeqc/](http://wwwbrr.cr.usgs.gov/projects/GWC_coupled/phreeqc/) and it is highly recommended to download as well the manual (<ftp://brrcftp.cr.usgs.gov/geochem/unix/phreeqc/manual.pdf>; 2.2 MB).

Both GUI's have the capability to start the PHREEQC program and to display the output file. Fig. 38 and Fig. 39 display how both appear for the user.

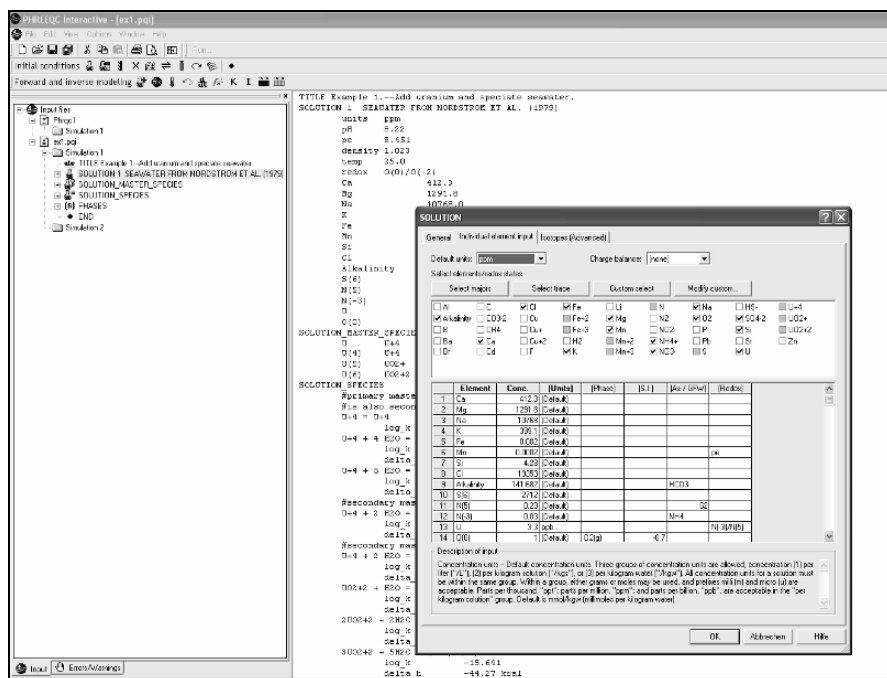

Fig. 38 Screenshot of PHREEQCI with the working spreadsheet to enter data for a solution

PHREEQCI has the advantage for novice user to offer icons for certain keywords (e.g.  for a solution) and to assist the user in terms of working spreadsheets and creating the input file from these spreadsheets. On the other hand, PHREEQC for Windows offers plotting results without transferring the data to external software (Excel, Origin etc.). So PHREEQCI might be better suited for very beginners while PHREEQC for Windows is the better choice for intermediate and advanced users. Readers may as well install both GUI's working with both versions parallel. Although PHREEQC for Windows is utilizing the input file extension .phrq and PHREEQCI the input file extension .pqj they can be used vice versa.

In this textbook we refer mainly to PHREEQC for Windows and its graphical capabilities. Therefore we will describe in the following briefly how to navigate through PHREEQC for Windows. After starting the program by click on PHREEQC.exe, a window with four templates opens: INPUT (chapter 2.2.1.1), DATABASE (chapter 2.2.1.2), GRID (chapter 2.2.1.4), and CHART (chapter 2.2.1.5). The template OUTPUT appears only after an input file has been run through PHREEQC and is thus available for displaying.

### 2.2.1.1 Input

The template Input consists of three windows (Fig. 39). The left, initially blank window is the active area to write the input file - a chemical analysis to be modeled together with the commands to perform the particular modeling task - by means of a simple text editor. PHREEQC keywords and PHREEQC BASIC statements are listed in the upper right window (window can be (in)activated under menu View/Keywords). A mouse click on the "+" symbol displays the list of keywords and subkeywords. The utilization of the BASIC commands is explained in chapter 2.2.2.3.2. The lower right window which can be (in)activated under menu View/Hints contains explanations for individual keywords from the keyword list above.

A simple input consists of the three keywords TITLE, SOLUTION and END. However, a simple job will also run using the keyword SOLUTION only. END is only required to separate multistage tasks. Anything written in the line beyond TITLE is for documentation purposes only. Keywords can generally be inserted to the left windows from the list on the right hand side by double clicking on the respective commands. For the keyword index three options can be chosen under Edit/Preference/Input in the main menu:

- Insert code templates from keywords index, e.g. for SOLUTION
 

```
SOLUTION 1-10
pH 6.05
pe 14.8
-units mg/L
Na 1 mmol/L
Cl 37 charge
C(4) 0.6 as HCO3
```
- Insert comments with templates (default setting upon initial installation), e.g. for SOLUTION
 

```
SOLUTION 1-10 # a number or a range of numbers. Default: 1.
pH 6.05 # Default: 7.
pe 14.8 # Default: 4.
-units mg/L # Default: mmol/kgw
Na 1 mmol/L # Chemical symbol from the 1st column in
              SOLUTION_MASTER_SPECIES, concentration,
              concentration is adapted to charge balance
Cl 37 charge # concentration is adapted to charge balance
C(4) 0.6 as HCO3 # Concentration is in mg of HCO3 = 0.6/0.61 =
                  0.98 mmol/L
```
- Insert templates as comments, e.g. for SOLUTION
 

```
#SOLUTION
```

The examples and explanations might be helpful for a beginner to understand the required syntax. For more advanced users, however, replacing the exemplary values gets tiresome and too many comments quickly render the input file confusing. Those users might wish to de-select all three options and will by double click on the keyword list only get the keyword as in previous versions of PHREEQC. A more helpful option might be to use the Hints window (menu View/Hints) in the lower right corner.

The structure of an input file will be explained by means of the example of the following seawater analysis (Fig. 39). The order of parameters and species in example SOLUTION 1 seawater analysis corresponds to a certain logic for instruction purposes. However, in general it does not matter in which order the details are entered in the input file. They only have to appear under the keyword SOLUTION.

**Fig. 39 PHREEQC Input file (example seawater analysis)**

To define the units for the input of concentrations the keyword "units" has to be used. Possible units are ppb and ppm or g, mg, and ug (not  $\mu\text{g}$ !) per Liter as well as mol, mmol, and umol per Liter or per kg water. Temperature (temp) is denoted in  $^{\circ}\text{C}$ . The density (density) can be entered in  $\text{g}/\text{cm}^3$ , with a default of 0.9998. That information is especially important for highly mineralized waters, like e.g. seawater. To insert the measured  $E_H$  value a conversion to the pE value is necessary (see chapter 1.1.5.2.2, Eq. 65). If no pE value is given, pE is assumed to be 4 by default. A redox couple (redox) can be defined to calculate the pE value that will be used to model the species distribution of redox-sensitive elements if no pE is given.

A list of element concentrations follows. Whereas ions like Ca, Mg, etc. that occur only in one redox state are indicated as elements, ions whose concentration is determined in different redox states are denoted individually with their valence in parentheses, as in the example Fe(3) and Fe(2). However, the syntax is defined in the database (\*.dat) not in the PHREEQC code. For complexes like  $\text{HCO}_3^-$ ,  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ , three input options exist:

[ion] ([valence]) [concentration in mg/L] **as** [complex form] *in the example for  $\text{HCO}_3^-$ ,  $\text{NH}_4$*

[ion] ([valence]) [concentration in mmol/L] **gfw**[molar mass of the complex]

*gfw = gram formula weight, in the example for  $\text{NO}_3^-$*

[ion] ([valence]) [concentration in mmol/L] **mmol/L** *in the example for  $\text{SO}_4^{2-}$*

In the latter case, mmol/L defines a unit different from the default unit defined under the subkeyword "units". It is important that the reference (in the example "liter") is the same as that used under the subkeyword "units". Alternatively, ppm could be defined generally under units and ppb for an individual element or mg/kgw (kg water) in general and mol/kgw for an individual element.

Furthermore, the command "**charge**" can be used with any element, the pH or the pE value, but it may **only** appear **once** in the whole input file (as in the example with chloride). The use of "**charge**" enforces a total charge compensation by means of the chosen element or the pH or the pE value, respectively and thus maintains electrical balance. The element with the highest concentrations might be chosen to keep the relative error as small as possible by means of an arbitrary increase or decrease of the concentration for charge compensation. The keyword "charge" may not be used with "Alkalinity".

The pH, pE, or individual elements may be combined with a mineral or gas phase and a saturation index (in the example: **O(0) 1.0 O2(g) -0.7**). It causes a change in concentration of the respective element to obtain equilibrium or a defined disequilibrium in terms of the defined mineral or gas phase. If no saturation index is given along with the phase name, the default SI = 0 (equilibrium) will be used. For gases, the logarithm of the partial pressure is specified in bar (instead of the saturation index for minerals): -0.7 in the example thus means a  $\text{O}_2$  partial pressure of  $10^{-0.7} = 0.2$  bar or 20 Vol-%.

If a redox couple is defined in the same line as an element, beyond the concentration input (in the example: **N(5)/N(-3)** beyond U) the species distribution (of uranium) is not calculated via the standard  $E_H$  value, but based on the redox equilibrium of the given redox couple.

The shortcut **STRG+T** opens a list of species defined in the database, **STRG+H** a list of minerals and gases defined in the database. Select the species or phase and press ENTER (no double click!) to transfer the selected species or phase to the position of the cursor in the input file.

Alternatively to the keyword SOLUTION, SOLUTION\_SPREAD can be used for the input of solutions. The input is transposed compared to the input for SOLUTION, i.e. the rows of input for SOLUTION become the columns of input for SOLUTION\_SPREAD. This tab-limited format is especially convenient to use

when more than one aqueous solution composition has to be defined. Data obtained e.g. from a laboratory spreadsheet format can be copied directly into the PHREEQC input file. SOLUTION\_SPREAD is compatible with the format of many spreadsheet programs, such as EXCEL. The column headings are element names, element valence state names or isotope names. One subheading can be used to define speciation (e.g. „as SO4“, or „as NO3“), specify element specific units, redox couples, phase names and saturation indices. All succeeding lines are the data values for each solution, with one solution defined in each line.

The extension “phrq” is linked with PHREEQC for Windows, however, when saving PHREEQC input files the extension has to be explicitly added to the file name, it is not added automatically. The input files are basically plain ASCII files that can be read and edited with any editor.

To model equilibrium reactions, kinetics, and reactive transport or to define additional data more keywords besides TITLE, SOLUTION, and END are available. In the following, their meanings are briefly described grouped into basic keywords that find a wide range of application by all users, keywords for defining data and for advanced modeling as well as very special keywords used by advanced users mainly. A complete list of keywords including a detailed description of individual input parameters and syntax is available in the PHREEQC manual (<ftp://brrcrftp.cr.usgs.gov/geochem/unix/phreeqc/manual.pdf>).

### Basic keywords

SOLUTION	REACTION
SOLUTION_SPREAD	REACTION_TEMPERATURE
TITLE	SAVE
DATABASE	USE
END	SELECTED_OUTPUT
EQUILIBRIUM_PHASES	USER_PUNCH
MIX	PRINT
GAS_PHASE	KNOBS

### Defining data

PHASES	EXCHANGE_MASTER_SPECIES
PITZER	EXCHANGE_SPECIES
LLNL_AQUEOUS_MODEL_PARA	EXCHANGE
METER	SURFACE_MASTER_SPECIES
SOLID_SOLUTIONS	SURFACE_SPECIES
SOLUTION_MASTER_SPECIES	SURFACE
SOLUTION_SPECIES	

### Advanced features

INVERSE_MODELING	ADVECTION
KINETICS	TRANSPORT
INCREMENTAL_REACTIONS	USER_GRAPH
RATES	USER_PRINT
	COPY

**Modeling isotopes**

ISOTOPES ISOTOPE_ALPHAS ISOTOPE_RATIOS	NAMED_EXPRESSIONS CALCULATE_VALUES
--	---------------------------------------

**Basic keywords**

**SOLUTION** defines the chemical composition of a water and is obligatory for any PHREEQC input file; without any subkeyword this would be distilled water.

**SOLUTION\_SPREAD** is an alternative input format for **SOLUTION** that is compatible with the output of many spreadsheet programs such as EXCEL

**TITLE** is used to include a comment for the simulation; additional comments can be added anywhere in the input data block after a „#“ sign

**DATABASE** can be used to overwrite the selected default database for an individual input file; if used it must be the first keyword in the input file

**END** defines the end of an input job; it is mandatory to conclude an initial modeling and re-use the modeled solutions in subsequent reactions within the same input job, e.g. it has to appear between the keywords **SAVE** and **USE**

**EQUILIBRIUM\_PHASES** is used to equilibrate a solution with either a solid phase or a gaseous phase (in an open system)

**MIX** can be used to mix one or more solutions in any ratios

**GAS\_PHASE** defines equilibrium with a gas phase in a closed system (in contrast to **EQUILIBRIUM\_PHASES** for open systems)

**REACTION** defines irreversible reactions which either add or remove specified amounts of elements to or from the aqueous solution

**REACTION\_TEMPERATURE** is used to model a range of different temperatures during a batch reaction; it overwrites any default temperature defined in **SOLUTION** and can be used as well in transport modeling

**SAVE** is used to save an interim result of the modeling for later use within the same input job; this can be e.g. the composition of a solution, a gas phase, or a surface

**USE** is used to recall previously saved interim results (compare **SAVE**)

**SELECTED\_OUTPUT** saves user-defined parameters in a file that is suitable for processing by spreadsheet programs

USER\_PUNCH prints user-defined results (written in a Basic program) to the SELECTED\_OUTPUT file as the modeling is running

PRINT can suppress the standard output or define which parameters are written to the standard output file

KNOBS is used to redefine parameters that cause numerical problems

### **Defining data**

PHASES can be used to define chemical reactions between solid and aqueous phases with their thermodynamic constants in the input file; its use is optional and overwrites default definitions in the database

PITZER specifies (equivalent to PHASES for the ion-association theory) thermodynamic constants if ion-interaction is used (Pitzer parameters); it overwrites definitions in the database file

LLNL\_AQUEOUS\_MODEL\_PARAMETER defines parameters for the LLNL aqueous model used in EQ3/6 and Geochemist Workbench, assembled in llnl.dat

SOLID\_SOLUTIONS is used to define a non-ideal (2 components) or ideal (>2 components) solid-solution assemblage

SOLUTION\_MASTER\_SPECIES defines the correspondence between the element and aqueous primary and secondary species (e.g. element: S; primary species:  $\text{SO}_4^{2-}$ ); it can be used optional in the input file to define additional or overwrite existing species from the database

SOLUTION\_SPECIES defines chemical reactions, thermodynamic constants, and activity coefficients for each species; it can be used optional in the input file to define additional or overwrite existing species from the database

EXCHANGE\_MASTER\_SPECIES defines correspondence between an exchange site and an exchange species; it can be used optional in the input file to define additional or overwrite existing species from the database

EXCHANGE\_SPECIES is used to define a half-reaction and relative log K for each exchange species

EXCHANGE defines the amount and composition of an assemblage of exchangers (either explicit by composition or implicit through equilibrium with a solution)

SURFACE\_MASTER\_SPECIES defines correspondence between a surface binding site and a surface master species; it can be used optional in the input file to define additional or overwrite existing species from the database

SURFACE\_SPECIES is used to define a reaction and log K for each surface species, including surface master species

SURFACE defines the amount and composition of an assemblage of surface binding sites (either explicit by defining the amounts of the surfaces in their neutral form or implicit through equilibrium with a solution); a surface assemblage may have multiple surfaces and each surface may have multiple binding sites

### **Advanced features**

INVERSE\_MODELING simulates the genesis of a given (final) solution from one or a mixture of multiple original solutions including any kind of equilibrium reactions with mineral or gas phases

KINETICS defines time-dependent (kinetic) reactions and specifies reaction parameters for batch-reaction and transport calculation

INCREMENTAL\_REACTIONS is used to save CPU time during kinetic batch-reactions

RATES allows to define any mathematical rate expressions for kinetic reactions by means of an integrated programming language (BASIC)

ADVECTION allows one-dimensional piston-flow with any chemical reaction offered by PHREEQC; dispersion and diffusion are not considered

TRANSPORT is used to simulate one-dimensional transport including advection, dispersion, diffusion, and diffusion to adjacent stagnant zones (double-porosity aquifers)

USER\_GRAPH plots user-defined results (written in a Basic program) to the tab CHART as the modeling is running

USER\_PRINT prints user-defined results (written in a Basic program) to the standard output file as the modeling is running

COPY copies a solution, mineral or gas phase, surface, etc., at the end of the simulation to one or a range of new index number(s)

### **Modeling isotopes**

ISOTOPES is used to define names, units, and absolute isotope ratio for individual minor isotopes

ISOTOPE\_ALPHAS prints calculated isotopic ratios defined with CALCULATE\_VALUES

ISOTOPE\_RATIOS prints the absolute ratio of minor to major isotope for each minor isotope and the ratio converted to standard measurement units.

NAMED\_EXPRESSIONS defines analytical expressions that are functions of temperature for isotopes

CALCULATE\_VALUES allows user-defined BASIC statements

### 2.2.1.2 Database

The databases WATEQ4F.dat, MINTEQ.dat, PHREEQC.dat and LLNL.dat are automatically installed with the program PHREEQC and can be chosen from the menu Calculations/File under Database File. Alternatively, the database can be defined for each input file by the keyword DATABASE followed by the file path. This overwrites any database selected by default via the menu Calculations/File. If the keyword DATABASE is used, it must be the first keyword in the input file.

The internal structure of thermodynamic databases has already been explained in detail in chapter 2.1.4.2 by means of the example WATEQ4F.dat. Lines beginning with “#” are only comments, e.g. each first line of reaction blocks under the keyword SOLUTION\_SPECIES.

When modeling rare elements, one will often recognize that not all necessary parameters are available in an existing database. Thus, there is theoretically the option to create/add own databases (e.g. as combination of different databases) or to change already existing ones. In chapter 2.1.4.1 and chapter 2.1.5, problems related to database maintenance, verification of database consistency or existence of species, and differences in the conditions under which the solubility constants have been determined, have already been discussed. Using the data browser of PHREEQC allows to view the selected database but not to edit it. If changes have to be made in the database (not recommended for beginners) this can be done with any external text editor, e.g. WORDPAD, and saved as ASCII file.

If elements, species, stability constants, and/or solubility constants that are unavailable in an existing database, are to be used for one job only, it is advisable to define them directly in the input file rather than to change the database itself. As a declaration in an input file always has a higher rank, it overwrites information of a database. Like in the database, the keyword SOLUTION\_MASTER\_SPECIES has to be used to define the element (e.g. C), the ionic form (e.g. CO3-2), the contribution of the element to alkalinity (e.g. 2.0), the mole mass of the species for the input in mg/L (e.g. 61.0171), and the atomic mass of the element (e.g. 12.0111) (see also Table 21). When entering the keyword SOLUTION\_SPECIES, a reaction, the respective solubility constant log k and the enthalpy delta h in kcal/mol or kJ/mol at 25 °C additionally have to be defined (for further operations see also Table 22), e.g.

Reaction	CO3-2 = CO3-2
Solubility constant	log k     0.0
Enthalpy	-gamma 5.4     0.0

### 2.2.1.3 Output

The modeling can be started either via Calculations/Start or by the icon “calculate”. A “PHREEQC for Windows-progress” window opens showing input, output and database file as well as the calculation progress in line 4. In the lower part calculation time and potential errors are displayed. DONE appears when the calculation is performed or terminated. By clicking on DONE, the progress window closes and the output folder opens.

An output file is automatically created with the name of the input file and the additional extension “out”. If one explicitly wants to enter a different name, it can be done under Calculations/Files Output-File. Editing in the output file is not possible (only via external text editor, but not recommended).

The output consists of a standard output plus additional results per input. The standard output has the following structure:

- Reading data base (the database including keywords is read)
- Reading input data (repetition of data and keywords from the input file)
- Beginning of initial solution calculation (standard calculations)
  - solution composition: element concentration in mol/kg (molality) and mol/L (moles)
  - description of solution: pH, pE, activity, charge balance, ionic strength, error of analysis, etc.
  - distribution of species: in each first line total concentration of an element in mol/L, followed by the species of that element with concentration  $c$  in mol/L, activity  $a$  in mol/L,  $\log c$ ,  $\log a$ , and  $\log \Gamma$  (=  $\log$  activity coefficient =  $\log (\text{activity}/\text{concentration}) = \log a - \log c$ ; see also chapter 1.1.2.4)
  - saturation indices: saturation indices with mineral name, SI,  $\log \text{IAP}$ ,  $\log \text{KT}$  ( $\text{SI} = \log \text{IAP} - \log \text{KT}$ ; see also chapter 1.1.4.1.2), and mineral formula; positive values mean super-saturation, negative values under-saturation with regard to the respective mineral phase.

If redox-sensitive elements (e.g.  $\text{NO}_3^-$ ,  $\text{NH}_4^+$  in the case of the seawater analysis) are declared in the input file, a paragraph “redox couples” will be displayed in the output after “description of solution” that contains all individual redox couples (in the example N(-3)/N(5)) with their respective partial redox potentials as pE, and  $E_H$  value in volts.

Following the standard output (beginning of initial solution calculation) the task-specific results are listed, i.e. this is now a modified solution not the initial solution anymore. The structure of the output file is displayed by an index in the window on the right. By double clicking on the tree structure one gets to the beginning of the chosen chapter in the output. Especially when searching long output files, the index is a significant help not to confound results from initial and modeled solutions.

### **2.2.1.4 Grid**

The GRID folder offers to plot data in spreadsheet format. However, a file name (“example.csv”) and the desired information has to be defined by using the command `SELECTED_OUTPUT` in the input file, e.g. the saturation indices of anhydrite and gypsum,

```
SELECTED_OUTPUT  
-file example.csv  
-si anhydrite gypsum
```

The spreadsheet file has to be opened manually in the folder GRID (does not happen automatically). Files with the extension “.csv” (Microsoft Excel files, delimited by comma) can be directly opened in the GRID folder. If no file name is entered in the command line, “selected.out” will be used as default. This file can be opened in GRID also, but is not displayed automatically (to open “selected.out” the file type “all files” (\*.\*) must be chosen). For other graphical representations it is recommended to open the `SELECTED_OUTPUT` file in a spreadsheet program (e.g. EXCEL) to make further changes and take advantage of graphical options in those programs.

### **2.2.1.5 Chart**

Data in the folder GRID can be highlighted and plotted in the CHART template by click on the right mouse button (“Plot in chart”). Values in the first selected column will be considered as x-values and all values in the following columns as y-values. A second possibility is using the keyword `USER_GRAPH` to define directly in the input file the parameters to be plotted in the CHART diagram (see exercise chapter 3.3.3).

Using the right mouse button, the diagram area can be formatted by “format chart area” (font, background). With “chart options”, it is possible to add a second y-axis, a legend, titles, and labels for the x- and y-axis. The axes, the legend, and the graph itself can be formatted by selecting and clicking the right mouse button.

## **2.2.2 Introductory Examples for PHREEQC Modeling**

### **2.2.2.1 Equilibrium reactions**

Equilibrium reactions (theory see chapter 1.1) are the simplest form of hydrogeochemical modeling. In the following, the modeling of such a reaction by means of PHREEQC is explained using four simple examples. For all calculations the database `WATEQ4F.dat` is used.

### 2.2.2.1.1. Example 1a standard output – seawater analysis

By means of the example of the seawater analysis already discussed in chapter 2.2.1.1 it is shown what kind of results can be obtained from the standard output. The corresponding PHREEQC input file can be found on the enclosed CD (PhreeqC\_files/0\_Introductory-Examples/1a\_Seawater-analysis.phrq).

General information is found in the paragraphs “**solution composition**” and “**description of solution**”. Solution composition shows that the water is of Na-Cl-type ( $\text{Cl} = 0.55 \text{ mol/L}$ ,  $\text{Na} = 0.47 \text{ mol/L}$ ; seawater).

The ionic strength of  $0.6594 \text{ mol/L}$  found in “description of solution” represents the high total mineralization of the seawater. To verify the accuracy of the analysis, the electrical charge balance and the analytical error are considered (electrical balance ( $\text{eq}$ ) =  $7.370 \cdot 10^{-04}$ ; percent error,  $100 \cdot (\text{Cat} - |\text{An}|) / (\text{Cat} + |\text{An}|) = 0.06$ ). Note: In Germany, the equation  $100 \cdot (\text{Cat} - |\text{An}|) / [0.5 \cdot (\text{Cat} + |\text{An}|)]$  is often used (Hölting 1996, DVWK 1990). This alternate form of the charge balance equation is also used in WATEQ4F (Ball and Nordstrom, 1991). Thus the error would be 0.12 %. Anyway, the accuracy of the analysis is very good and the analysis can be used for further modeling. If the command “charge” is put behind chloride, as shown in the example in chapter 2.2.1.1, a total charge compensation will be enforced [electrical balance ( $1.615 \cdot 10^{-16}$ ) and analytical error (0.00)]. Under “redox couples” the redox potential for each single redox couple is listed as  $\text{pE}$ - or  $\text{E}_\text{H}$  value.

Not only the total concentration of each element can be taken from “distribution of species” but also the distribution of species, i.e. the share of free cations, negatively charged, positively charged, and non-charged complexes. With this information it is possible to draw conclusions about oxidative/reductive ratios, mobility, solubility, or even toxicity of elements and species. The cations Na, K, Ca, and Mg mainly exist (87-99 as free cations, only 1-13 % account for metal-sulfate-complexes. Chloride predominates as free ion to nearly 100 %. It hardly reacts with other bonding partners. C(4) occurs predominantly as  $\text{HCO}_3^-$  ion (70 %), yet reacts to a lower percentage with Mg and Na forming  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$  complexes. S(6) behaves similar to C(4) forming predominantly  $\text{SO}_4^{2-}$ . N(5) and N(-3) occur predominantly as  $\text{NO}_3^-$  and to a less amount as  $\text{NH}_4^+$ . The easiest way to picture species distribution is a pie chart. Fig. 40 shows exemplary the species distribution for C(4) and S(6).

Fig. 40 EXCEL pie charts to represent the species distribution of S(6) and C(4)

The ratio N(5)/N(-3) is approximately 3:1. The Fe(3)/Fe(2) ratio is 4:1. It is important to consider that the predominant Fe(2) species are  $\text{Fe}^{2+}$  and the positively charged complex  $\text{FeCl}^+$  which are subject to cation exchange. On the other hand, Fe(3) occurs mainly as non-charged complex  $\text{Fe}(\text{OH})_3^0$  and is thus hardly retained at all. U(6) clearly dominates compared to U(5) and U(4). In contrast to U(4), U(6) is considerably more soluble and thus more mobile. But the predominant U(6) species are the negatively charged complexes  $(\text{UO}_2(\text{CO}_3)_3)^{4-}$ ,  $\text{UO}_2(\text{CO}_3)_2^{2-}$ , which are subject to interactions with e.g. iron hydroxides. Mobility may thus be limited. The different ratios of reduced to oxidized species for N, Fe, and U are in accordance with the theoretical oxidation/reduction succession (see also Fig. 21). The oxidation of Fe(2) to Fe(3) already starts at pE values of 0, the oxidation of N(-3) to N(5) only at pE= 6, while the oxidation of uranium is already finished at a pE value of 8.451, which was determined in the seawater sample.

Hints for super- or undersaturation of minerals can be found in the last paragraph of the initial solution calculations entitled “saturation indices”. Graphical representation of saturation proportions is often done by means of bar charts, where SI = 0 marks the point of intersection between the x-axis and the y-axis, and the bars of super-saturated phases point upwards and those for under-saturated phases downwards (example Fe-bearing mineral phases Fig. 41).

**Fig. 41 EXCEL bar chart to represent all super- and undersaturated iron-bearing mineral phases**

It is important to note that not all mineral phases with an SI > 0 necessarily will precipitate because slow reaction rates and prevailing boundary conditions may lead to the preservation of disequilibria over long periods. Therefore, dolomite will not precipitate from seawater despite its distinctly positive SI of 2.37 (or 1.82

for dolomite(d); d = dispersedly distributed) due to its inertness. In contrast to this, a rapid precipitation can be expected for calcite with an SI of 0.74. Referring to the iron represented in Fig. 41, a fast precipitation reaction of amorphous iron hydroxide can be anticipated. Thereby, only a moderate super-saturation occurs (SI = +0.18). Pyrite is significantly supersaturated and will likely precipitate with time, after amorphous iron hydroxide, forming finely distributed crystals. Hematite, magnetite, and goethite are generally formed from  $\text{Fe}(\text{OH})_3(\text{a})$  during conversion reactions and will not precipitate directly. Altogether, it can be observed that the total concentration of iron with  $\text{Fe} = 0.0025 \text{ mg/L}$  is very low and thus not sufficient for all precipitation reactions to reach equilibrium.

#### 2.2.2.1.2. Example 1b equilibrium – solution of gypsum

The question “How much gypsum can be dissolved in distilled water?” shall be answered by manual calculation and then by means of PHREEQC for comparison [pK gypsum = 4.602 (at  $T = 20^\circ\text{C}$ )].

##### Calculation

The chemical equation for the dissolution of gypsum is:

$$K_{\text{gypsum}} = \frac{\{\text{Ca}^{2+}\} \cdot \{\text{SO}_4^{2-}\}}{\{\text{CaSO}_4\}}$$

$$K = [\text{Ca}^{2+}] \cdot [\text{SO}_4^{2-}] = 10^{-4.602} \quad (\text{as } [\text{CaSO}_4] = 1)$$

$$\text{as } [\text{Ca}^{2+}] = [\text{SO}_4^{2-}] \quad K = [\text{SO}_4^{2-}]^2 \quad [\text{SO}_4^{2-}] = \mathbf{0.005 \text{ mol/L} = 5 \text{ mmol/L}}$$

This result calculated based on the mass-action law is, however, not a concentration but an activity (chapter 1.1.2). The conversion from activity to concentration is carried out using the activity coefficient (Eq. 10). The ionic strength is calculated according to Eq.12:

$$I = 0.5 \cdot \sum m_i \cdot z_i^2$$

where  $m$  is the concentration in mol/L and  $z$  the oxidation state of the species  $i$ . Since the concentration is unknown, iterative calculation has to be performed with a first approximation that the activity of 5 mmol/L replaces the concentration. The results for  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$  are:

$$I = 0.5 \cdot \sum 5 \cdot 2^2 + 5 \cdot 2^2 = 20 \text{ mmol/L}$$

From the graphical correlation between ionic strength and activity coefficient (Fig. 2) an activity coefficient  $f_1$  of about 0.55 and a concentration  $c_1$  of  $a_i/f_i = 0.005/0.55 = 0.009 \text{ mol/L} = 9 \text{ mmol/L}$ , respectively is found. If this first approximation for the concentration is now used in the equation for the ionic strength, the following results will be obtained:  $I_2 = 36 \text{ mmol/L}$ ,  $f_2 = 0.5$ ,  $c_2 =$

0.010 mol/L = 10 mmol/L;  $I_3 = 40$  mmol/L,  $f_3 = 0.48$ ,  $c_3 = 0.0104$  mol/L = 10.4 mmol/L, etc. With three iterative steps a concentration of about **10 mmol/L of gypsum is calculated.**

### Modeling

In comparison to this calculation, the dissolution of gypsum in distilled water shall now be modeled by means of PHREEQC. The input is very simple as it concerns distilled water and thus, the SOLUTION block contains only pH = 7 and temperature = 20 °C. To enforce equilibrium with gypsum, the keyword EQUILIBRIUM\_PHASES and a saturation index of 0 are used.

The input file looks as follows (1b\_Solution-of-gypsum.phrq):

```
TITLE example 2 dissolution of gypsum
SOLUTION 1
      temp          20
      pH            7.0
EQUILIBRIUM_PHASES
gypsum  0
END
```

The output file contains an additional block “beginning of batch-reaction calculations”, and a “phase assemblage” block besides the already known paragraphs solution composition, description of solution, distribution of species, saturation indices. Phase assemblage contains: mineral phase – SI – log IAP – log KT – initial (initial amount of gypsum, 10 mol/kg by default) – final (amount of gypsum, which still exists as solid after dissolution) – delta (amount of dissolved gypsum = final - initial; negative value stands for dissolution, positive values indicate precipitation).

As distilled water (with no constituents) is used, the amount of dissolved gypsum (phase assemblage delta) is equal to the amount of  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$  (solution composition molality, respectively distribution of species).

The result of the dissolution of gypsum is  $1.532 \cdot 10^{-2} = \mathbf{15.32 \text{ mmol/L}}$ , in comparison to about 10 mmol/L of the preceding calculation. Looking at the species distribution it can be seen that besides the free ions  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$  the following complexes have been formed as well:  $\text{CaSO}_4^0$ ,  $\text{CaOH}^+$ ,  $\text{HSO}_4^-$  and  $\text{CaHSO}_4^+$ . Due to the formation of the  $\text{CaSO}_4^0$  complex (**4.949 mmol/L**), the dissolution of gypsum will be clearly increased (see also chapter 1.1.4.1.1). It is a process that had not been considered in the simple manual calculation above.

Already, by means of this first simple example, the complexity of describing the hydrogeochemistry of aquatic systems and the limitations of interpretations without computer-aided modeling can be understood.

#### 2.2.2.1.3. Example 1c equilibrium – solution of calcite with $\text{CO}_2$

Besides modeling a simple equilibrium as in the previous example, the keyword EQUILIBRIUM\_PHASES also allows to model any disequilibrium with minerals

or gases. To model this, a more detailed look at the syntax is necessary. The syntax of lines following the keyword `EQUILIBRIUM_PHASES` is *name*, *SI*, *moles*, *option*. As explained before, *name* is the name of the mineral or gas (as defined in the database used), *SI* is the desired saturation index for the minerals. In case of gases, this value is the logarithm of the desired partial pressure in bar (0.01 bar  $\rightarrow$  -2). *Moles* is the amount of moles which can be dissolved (default 10 mol); by setting moles to 0.0 only precipitation of the mineral is allowed. If only dissolution is required this can be set by adding the statement *diss* as option at the end of the line.

These options will be demonstrated in the following example (1c\_Solution-of-calcite-CO2.phrq). If rainwater comes into contact with calcite assuming a certain CO<sub>2</sub> partial pressure this can be modeled as shown in the upper part of input file example 2b. The second part after the first END describes what happens if this water then comes into contact with dolomite. By setting Calcite 0.2 0 PHREEQC maintains a SI of 0.2 (slightly oversaturated); the 0 provides that no calcite will be dissolved. Thus, incongruent dissolution of minerals can be modeled very easily in PHREEQC. The third part in the input file provides the dissolution of gypsum; this will also lead to a secondary formation of calcite which is again handled by setting *moles* to zero.

Title example 2b dissolution calcite & dolomite

Solution 1 # distilled water ~ rain water

temp 20

pH 6.4

EQUILIBRIUM\_PHASES

Calcite 0 # assume contact with calcite

CO2(g) -2 # and a CO2 partial pressure of 1% = 0.01 bar

O2(g) -0.68 # used to equilibrate with O2 of air

SAVE SOLUTION 1

END # end of first job

USE SOLUTION 1

EQUILIBRIUM\_PHASES # assume contact with dolomite

Dolomite 0 10 diss # SI=0, 10 moles available, only dissolution!

CO2(g) -2

O2(g) .00001

Calcite 0.2 0 # SI=0.2 (slightly oversaturated), 0 mol  $\rightarrow$  no dissolution

SAVE SOLUTION 2

END

USE SOLUTION 2

EQUILIBRIUM\_PHASES # assume contact with gypsum

Gypsum 0

Calcite 0.2 0

END

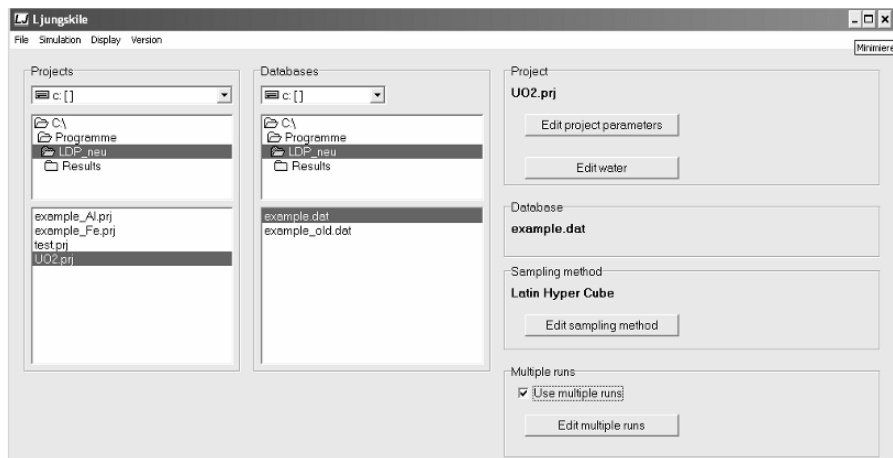

Fig. 42 shows the change in concentrations of calcium, magnesium, sulfate, and total inorganic carbon (TIC) during the three steps of contact with different minerals.

**Fig. 42 Development of water quality of rainwater after subsequent contact with calcite, dolomite, and gypsum assuming 1% CO<sub>2</sub> partial pressure of soil gas. Negative values indicate precipitation (of calcite) due to incongruent dissolution of dolomite and gypsum.**

#### 2.2.2.1.4. Example 1d: Modeling uncertainties – LJUNGSKILE

As mentioned before (chapter 2.1.5), results of thermodynamical or kinetic modeling depend significantly on thermodynamic stability constants or reaction rates. PHREEQC does not offer an option to evaluate this aspect except for manually changing parameters within a range from minimum to maximum. However, if more than one parameter is changed the number of necessary permutations is growing rapidly. The probabilistic speciation code LJUNGSKILE (Odegard-Jensen et al 2004) couples PHREEQC with either a Monte Carlo or a Latin Hypercube Sampling (LHS) approach to allow calculation of species diagrams with uncertainties. Species diagrams can be plotted by means of a chart template using LDP20.exe or via export to any scientific chart software. LJUNGSKILE and the viewing tool LDP20 can be downloaded from <http://www.geo.tu-freiberg.de/software/Ljungskile/index.htm>. Both programs install automatically and can be started showing the following template:

A new project is created in LJUNGSKILE via **File/new**. Then a database has to be selected. This can be any valid PHREEQC database, however, two theoretical species must be included which are used by LJUNGSKILE to maintain electrical charge balance. These changes have to be made using any text editor.

#### SOLUTION\_MASTER\_SPECIES

Im	Im	0.000000	Im	40.000000

      delta_h 0.000000 kcal
  
```

Alternatively, the database example.dat can be used which is a modified Phreeqc.dat file and is created by the installation routine. Then, the species of interest have to be edited via **Edit project parameters**.

**Project parameters**

☐ Solid phase  Amount (mole)

☐ CO2(g) Partial pressure (bar)

Species	Name	Mean value	SD or max value	Distribution
	UO2(SO4)2-2	4.14	0.2	Normal
	UO2+2	9.04	0.2	Normal
	UO2SO4	3.15	0.2	Normal
	UO2CO3	9.63	0.2	Normal
	UO2(CO3)2-2	17	0.2	Normal
	UO2(CO3)3-4	21.63	0.2	Normal
	UO2(OH)3-	-19.2	0.2	Normal

Close edit project parameters

In the column “mean value” the log<sub>k</sub> values from the database used have to be entered for the species of interest. The distribution for LHS or Monte Carlo simulation can be defined as “normal” distributed, then the assumed standard deviation of the log<sub>k</sub> is entered in the column “SD or max value”. Alternatively, one can enter “uniform” in distribution and enter a maximum value of log<sub>k</sub> in the column “SD or max value”. Alternatively, a solid phase and the partial pressure of carbon dioxide can be entered. LJUNGSKILE will then maintain equilibrium with the mineral entered and the carbon dioxide partial pressure by means of EQUILIBRIUM\_PHASES. Additionally, the master species of the solution has to be entered in the template **edit water**. The same template is used to define the pH, pe, and temperature.

**Water description**

Groundwater properties

Description

pH

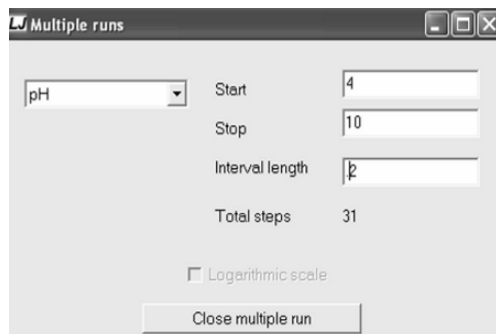

pe

Temperature (C)

Name	Concentration
Ca	0.002
S	0.002
C	0.002
U	1E-5
P	5E-6

EXIT

Edit sampling method is used to choose between LHS (Latin Hypercube Sampling) and Monte Carlo Sampling. Finally, LJUNGSKILE offers to calculate species concentrations at the given pH or by changing one parameter (e.g. pH or pe) within a certain range. This is done by checking in the multiple run box and edit the range and the interval length.

LJUNGSKILE can be started from the GUI with “simulation” from the main menu. Output is written in files named species.out respectively PHROUT.number with number running from 1 to the total number of e.g. pH steps. For visualization, the visualization tool LDP20.exe can be used either by Display from the LJUNGSKILE main menu or directly from the folder where LDP20.exe is installed. For high quality plots and plots according to the user’s desires data can be imported to any spreadsheet for further evaluation.

**Fig. 43** Concentration of the four most dominant uranium species as function of pH with mean values (solid lines) and  $\pm$  standard deviation (dashed lines)

Fig. 43 was generated by calculating the mean value and standard deviation (SD) for all uranium species in the solution and all pH permutations. The plot shows thus the mean concentrations and mean value plus SD respectively mean value minus SD. The file UO2.prj generating the data for this example is enclosed on the CD of the book. It will run only with the example.dat from the book's CD because this is a renamed Wateq4f.dat (containing uranium data) with the necessary modifications as mentioned above.

### 2.2.2.2 Introductory example for sorption

The capability of PHREEQC to deal with sorption will be demonstrated in three examples. The first one is using the cation ion exchange approach, the second one DDLM (diffuse double-layer model), and the third one CD-MUSIC (charge distribution multisite complexation). Both DDLM and CD-MUSIC are surface-complexation models.

If exchange shall be modeled three keywords are needed: EXCHANGE\_MASTER\_SPECIES, EXCHANGE\_SPECIES, and EXCHANGE. In some databases installed with the PHREEQC package "exchange"-data are included (Table 24); however, these data are only examples and have to be replaced by site-specific data. This can be done in the *name.dat* file with any text-editor or in the input file, as this overwrites information from the .dat-file.

**Table 24** Default data for cation exchange and surface complexation with respect to databases installed with PHREEQC

	cation exchange	surface complexation (diffuse double-layer model)
Phreeqc.dat	Na <sup>+</sup> , K <sup>+</sup> , Li <sup>+</sup> , NH <sub>4</sub> <sup>+</sup> , Ca <sup>2+</sup> , Mg <sup>2+</sup> , Sr <sup>2+</sup> , Ba <sup>2+</sup> , Mn <sup>2+</sup> , Fe <sup>2+</sup> , Cu <sup>2+</sup> , Zn <sup>2+</sup> , Cd <sup>2+</sup> , Pb <sup>2+</sup> , Al <sup>3+</sup>	H <sub>3</sub> BO <sub>3</sub> , Ba <sup>2+</sup> , CO <sub>3</sub> <sup>2-</sup> , Ca <sup>2+</sup> , Cd <sup>2+</sup> , Cu <sup>2+</sup> , F <sup>-</sup> , Fe <sup>2+</sup> , Mg <sup>2+</sup> , Mn <sup>2+</sup> , PO <sub>4</sub> <sup>3-</sup> , Pb <sup>2+</sup> , SO <sub>4</sub> <sup>2-</sup> , Sr <sup>2+</sup> , Zn <sup>2+</sup>

Minteq.V4.dat	-	Ag <sup>+</sup> , H <sub>3</sub> AsO <sub>3</sub> , H <sub>3</sub> AsO <sub>4</sub> , H <sub>3</sub> BO <sub>3</sub> , Ba <sup>2+</sup> , Be <sup>2+</sup> , Ca <sup>2+</sup> , Cd <sup>2+</sup> , CN <sup>-</sup> , Co <sup>2+</sup> , Cr(OH) <sub>2</sub> <sup>+</sup> , CrO <sub>4</sub> <sup>2-</sup> , Cu <sup>2+</sup> , Hg(OH) <sub>2</sub> , Mg <sup>2+</sup> , MoO <sub>4</sub> <sup>2-</sup> , Ni <sup>2+</sup> , PO <sub>4</sub> <sup>3-</sup> , Pb <sup>2+</sup> , SO <sub>4</sub> <sup>2-</sup> , Sb(OH) <sub>6</sub> <sup>-</sup> , SeO <sub>4</sub> <sup>2-</sup> , SeO <sub>3</sub> <sup>2-</sup> , Sn(OH) <sub>2</sub> , VO <sub>2</sub> <sup>+</sup> , Zn <sup>2+</sup>
LLNL	Na <sup>+</sup> , K <sup>+</sup> , Li <sup>+</sup> , NH <sub>4</sub> <sup>+</sup> , Ca <sup>2+</sup> , Mg <sup>2+</sup> , Sr <sup>2+</sup> , Ba <sup>2+</sup> , Mn <sup>2+</sup> , Fe <sup>2+</sup> , Cu <sup>2+</sup> , Zn <sup>2+</sup> , Cd <sup>2+</sup> , Pb <sup>2+</sup> , Al <sup>3+</sup>	Ba <sup>2+</sup> , H <sub>3</sub> BO <sub>3</sub> , Ca <sup>2+</sup> , Cd <sup>2+</sup> , Cu <sup>2+</sup> , F <sup>-</sup> , Fe <sup>2+</sup> , Mg <sup>2+</sup> , Mn <sup>2+</sup> , PO <sub>4</sub> <sup>3-</sup> , Pb <sup>2+</sup> , SO <sub>4</sub> <sup>2-</sup> , Sr <sup>2+</sup> , Zn <sup>2+</sup>

At least one exchange master species has to be defined in the following manner:

#### EXCHANGE\_MASTER\_SPECIES

```
X   X-           # X has one negative load
Y   Y-2          # Y has a twofold negative load
```

X and Y are arbitrary names: X (without charge), X- (with charge). Furthermore, the exchange species has to be defined by the keyword EXCHANGE\_SPECIES:

#### EXCHANGE\_SPECIES

```
X- = X-
log_k   0           # dummy log_k
Na+ + X- = NaX      # define new exchange_species
log_k   0.0         # per definition 0.0 for the first cation
-gamma  4.0         0.075 # define activity coefficient
Ca+2 + 2X- = CaX2
log_k   0.5         # log_k relative to NaX.
-gamma  5.0         0.165 # define activity coefficient
.....
```

Finally, there are several options to define the modeling task by using the keyword EXCHANGE:

```
EXCHANGE 1-10          # calculate exchange for cells 1 to 10
X         1.5          # moles on the exchanger
Y         0.2
-equilibrate 5         # calculate initial equilibrium with solution 5
or
EXCHANGE 11            # measured exchange composition of cell 11
CaX2      0.3          # 0.3 moles Ca
NaX       0.5          # 0.5 moles Na → 2 · 0.3 + 0.5 = 1.1 moles X
```

For more complex options to define the initial exchange composition we refer to the PHREEQC manual. A very simple example for an exchange calculation is given in the following PHREEQC input file (2a\_Sorption\_exchange.phrq):

DATABASE WATEQ4F.dat	# use of WATEQ4F.dat is required !
TITLE Exchange example	
SOLUTION 1	
units	umol/kgw
pH	6
Cd	1
Pb	10
Zn	10
Cl	40
EXCHANGE 1	# calculate exchange for solution 1
CaX2	0.3 # 0.3 moles Ca.
NaX	0.5 # 0.5 moles Na. Sum= 2·0.3 + 0.5 = 1.1 moles X.
END	

In this case, only the keyword EXCHANGE is used since as mentioned above the definition of EXCHANGE\_MASTER\_SPECIES and EXCHANGE\_SPECIES is included in WATEQ4F.dat. The task of this job is simply to calculate the exchange reaction of a given solution 1 (1 liter) with a certain amount of a clay mineral (volume defined by 1.1 moles total exchange capacity). Be aware that the selectivity coefficients ( $\log_k$  for exchange species) in the WATEQ4F.dat are just functors and not valid for real aquifer material. Running the input file will show a resulting pH of 9.4 and completely changed composition for solution 1:

Na	69.39	$\mu\text{mol/L}$	Cd	$8.396 \cdot 10^{-9}$	$\mu\text{mol/L}$
Cl	40.0	$\mu\text{mol/L}$	Pb	$3.887 \cdot 10^{-6}$	$\mu\text{mol/L}$
Ca	$2.016 \cdot 10^{-03}$	$\mu\text{mol/L}$	Zn	$5.935 \cdot 10^{-6}$	$\mu\text{mol/L}$

For modeling **surface complexation** PHREEQC offers four models:

- A generalized two-layer model with no explicit calculation of the diffuse-layer composition.
- an electrostatic double layer model with explicit calculation of the diffuse-layer
- a non-electrostatic model
- CD-MUSIC

For a surface complexation approach in PHREEQC three keywords are essential: SURFACE, SURFACE\_MASTER\_SPECIES, and SURFACE\_SPECIES. The definition of a surface master species is comparable to that of an exchange master species and given names are arbitrary as well. A surface consists of one or more binding sites and as many surfaces as necessary can be defined.

As already mentioned some databases installed with the PHREEQC software contain definitions (Table 24) based on a diffuse double-layer model (2pK model) and data for ironhydroxides (Dzombak and Morel, 1990). The surface is named “Hfo” (Hydrous ferric oxide) containing two sites: a strong binding site, Hfo\_s, and a weak binding site, Hfo\_w. Dzombak and Morel (1990) used 0.2 mol for the weak sites and 0.005 mol for the strong sites per mol Fe, a surface area of  $5.33 \cdot 10^4 \text{ m}^2/\text{mol Fe}$ , and a gram-formula weight of 89 g Hfo/mol Fe.

#### SURFACE\_MASTER\_SPECIES

Hfo_s	Hfo_sOH	# strong binding site	Hfo_s
Hfo_w	Hfo_wOH	# weak binding site	Hfo_w

#### SURFACE\_SPECIES

Hfo_sOH = Hfo_sOH	# strong binding site	Hfo_s
$\log_k$ 0.0	# dummy	
Hfo_wOH = Hfo_wOH	# weak binding site	Hfo_w
$\log_k$ 0.0	# dummy	
Hfo_sOH + H+ = Hfo_sOH2+	# additional surface complexes	
$\log_k$ 7.29	# pKa1	

```

Hfo_sOH = Hfo_sO- + H+
log_k   -8.93                # -pKa2

Hfo_wOH + H+ = Hfo_wOH2+
log_k    7.29                # = pKa1

Hfo_wOH = Hfo_wO- + H+
log_k   -8.93                # = -pKa2

Hfo_sOH + Ca+2 = Hfo_sOHCa+2
log_k    4.97

Hfo_wOH + Ca+2 = Hfo_wOCa+ + H+
log_k   -5.85

.....

```

The complete list of surface complexation reaction defined in the selected database, e.g. WATEQ4F.dat or one of the other .dat files, can be viewed by click on the subfolder DATABASE. A simple example is given in the following introductory example (2b\_Sorption\_surface\_complexation\_UO2.phrq). The task is to simulate the scavenging of uranium by formation of ironhydroxides when a reduced acid mine water is treated with oxygen and limestone. The script contains three jobs which are separated by an END keyword.

```

DATABASE WATEQ4F.dat
TITLE sorption of uranyl on precipitated ironhydroxides
SOLUTION 1    acid mine water containing 2380 ppb Uranium
    pH  3
    pe  4
    units mmol/kgw
    Fe  2
    S   2.635
    U   10 umol/kgw
END
USE SOLUTION 1
EQUILIBRIUM_PHASES 1  # equilibrate with calcite and oxygen
    Calcite  0
    O2(g)  0.0001
SAVE SOLUTION 1
END
USE SOLUTION 1          # equilibrate Fe(OH)3(a) + perform surface complexation
SURFACE 1
    Hfo_wOH          Fe(OH)3(a) equilibrium_phase 0.2      5e4
    # weak site coupled to Fe(OH)3(a), 0.2= proportionality factor, surface (m2/g)

    Hfo_sOH          Fe(OH)3(a) equilibrium_phase 0.005
    # strong site coupled to Fe(OH)3(a), 0.005 = proportionality factor
EQUILIBRIUM_PHASES 1
    Fe(OH)3(a)  0 0
END

```

The proportionality factor in the definition of SURFACE 1 states the moles of this surface site per mole of the phase. This form of defining the surface accounts for the amount of iron hydroxides precipitated (2 mmol) in step 3 of the job. Thus more or less no iron remains in solution and 8.133  $\mu\text{mol/L}$  (81.33%) of uranium are removed due to surface complexation; the composition of surface species is given in Table 25. For more details run the introductory file and check the output.

**Table 25 Results of surface complexation divided into strong and weak binding sites**

strong site: $1 \cdot 10^{-5}$ moles 0.005 mol/(mol $\text{Fe}(\text{OH})_{3(a)}$ )	$\mu\text{mol}$	weak site: $4 \cdot 10^{-4}$ moles 0.2 mol/(mol $\text{Fe}(\text{OH})_{3(a)}$ )	$\mu\text{mol}$
<b>Hfo_sOUO2+</b>	<b>4.322</b>	Hfo_wOH	180.8

		Hfo_wO-	5.616
		<b>Hfo_wOUO2+</b>	<b>3.811</b>
		Hfo_wOCa+	0.3752

Because there is no database available so far containing CD-MUSIC parameters three surface complexes are defined in the following examples according to data from Hiemstra and Riemsdijk (1999) for the surface complexation of arsenate on goethite. Based on IR spectrometry and similarities to phosphate they stated a monodentate, a bidentate, and a protonated bidentate species:

In the above equations p and q are the charges present on the inner and outer oxygens, respectively. The values can be calculated from the CD values. For details of the calculation see Hiemstra and Riemsdijk (1996, 1999). In the input file (2c\_Sorption\_surface\_complexation\_CD-MUSIC.phrq) only these three surface complexation species are defined; then first a solution without arsenic is applied followed by a solution containing 1 mmol/L arsenic. Each time the pH is fixed on values between 3 and 11. Concentration of Na and Cl was set to 1000 mmol/L. The semicolon is used here as an equivalent for carriage return (new line) in order to make the file as compact as possible. Replacing semicolons by carriage returns the script might be easier to read for beginners.

Fig. 44 shows the amount of arsenic sorbed versus pH. Sorption takes place in particular as protonated bidentate species and to a minor share as the monodentate species. The non-protonated bidentate species has no significant share. Although no definitions were made for the surface complexation of  $\text{Cl}^-$  and  $\text{Na}^+$  in this simplified example the result changes significantly by setting the concentration of Na and Cl e.g. to 100 mmol/L.

Fig. 44 Sorption of arsenic on goethite according to CD-MUSIC model

### 2.2.2.3 Introductory examples for kinetics

Advanced modeling includes modeling of kinetically controlled processes (for theory see chapter 1.2). Normally the reaction rate varies with the reaction process and this leads to a set of simple differential equations. The integration of the reaction rates over time can be carried out e.g. with the help of the Runge-Kutta algorithm. The implementation of Fehlberg (1969) within PHREEQC offers the possibility to evaluate the derivatives in partial steps by performing error estimation and comparing it with a user-predetermined tolerance limit (Cash & Karp 1990).

For kinetic modeling in PHREEQC two keywords are necessary: KINETICS n (n = number of SOLUTION, for which the kinetics shall be calculated) and RATES. For both keywords, a “rate name” has to be entered, e.g. calcite when the dissolution of calcite shall be modeled kinetically. The general syntax within the keyword KINETICS is shown in Table 26.

**Table 26 Syntax within the keyword kinetics in PHREEQC**

KINETICS m-n	[m<n]
rate name	<i>rate name</i> and its associated rate expression must be defined within a RATES data block, e.g. pyrite, or any aquatic species
-formula	chemical formula or the name of a phase
-m	current moles of reactant [default = m0]
-m0	initial moles of reactant
-parms	a list of numbers may be entered that can be used in a BASIC program within the rate expressions, for example constants, exponents, or half-saturation constants
-tol	Tolerance for integration procedure [default = $1 \cdot 10^{-8}$ mol/L], the value of <i>tolerance</i> is related to the concentration differences that are considered significant for the elements in the reaction. Smaller concentration differences that are considered as significant require smaller tolerances.
-steps	Time steps over which the rate expressions is integrated, n in m steps [default: n = 1] in seconds, e.g. 500 in 3 steps or 100 300 500
-step_divide	If <i>step_divide</i> is greater than 1.0, the first time interval of each integration is set to <i>time</i> = step/step_divide; if step_divide is less than 1.0, then <i>step_divide</i> is the maximum moles of reaction that can be added during a kinetic integration subinterval.
runge_kutta	(1,2,3 or 6) designates the preferred number of time subintervals to use when integrating (default 3)

The general syntax for RATES is “rate name”, -start, and -end. A BASIC program is obligatory between -start and -end (see chapter 2.2.2.3.1).

## 2.2.2.3.1. Defining reaction rates

As reaction rates can be fitted mathematically in very different manners, there is an option (and need) in PHREEQC to declare any mathematical term in the form of a little BASIC program within the keyword RATES as will be shown in the following example of a **time-dependent calcite dissolution** (3\_Kinetics-solution-of-calcite.phrq):

SOLUTION 1 distilled water

pH 7

temp 10

EQUILIBRIUM\_PHASES

CO2(g) -3.5

KINETICS 1

Calcite

-tol 1e-8

-m0 3e-3

-m 3e-3

-parms 50 0.6

-steps 36000 in 20 steps // 36.000 seconds\*

-step\_divide 10000 // first interval calculated with 3.6 sec.\*

RATES

Calcite

-start

1 rem Calcite solution kinetics according to Plummer et. al 1978

2 rem parm(1) = A/V, 1/dm parm(2) = exponent for m/m0

10 si\_cc = si("Calcite")

20 if (m <= 0 and si\_cc < 0) then go to 200

30 k1 = 10^(0.198 - 444.0/(273.16 + tc) )

40 k2 = 10^(2.84 - 2177.0/(273.16 + tc) )

50 if tc <= 25 then k3 = 10^(-5.86 - 317.0/(273.16 + tc) )

60 if tc > 25 then k3 = 10^(-1.1 - 1737.0/(273.16 + tc) )

70 t = 1

80 if m0 > 0 then t = m/m0

90 if t = 0 then t = 1

100 moles = parm(1) \* 0.1 \* (t)^parm(2)

110 moles = moles \* (k1 \* act("H+") + k2 \* act("CO2") + k3 \* act("H2O"))

120 moles = moles \* (1 - 10^(2/3\*si\_cc))

130 moles = moles \* time //this line is a "must" for each BASIC-program\*

140 if (moles > m) then moles = m

150 if (moles >= 0) then goto 200

160 temp = tot("Ca")

170 mc = tot("C(4)")

180 if mc < temp then temp = mc

190 if -moles > temp then moles = -temp

200 save moles //this line is a "must" for each BASIC-program\*

-end

## SELECTED\_OUTPUT

-file 4\_Calcite.csv

-saturation\_indices calcite

end

\* the '//' included comments cannot appear like this in a PHREEQC-BASIC script as the BASIC interpreter is trying to interpret them. It is only possible by means of REM (remark) to include commentary lines at the beginning of a line.

Fig. 45 shows that the calcite equilibrium is attained very rapidly at low CO<sub>2</sub> partial pressures (in the example 0.03 Vol-%), but distinctly slower at increased CO<sub>2</sub> partial pressures (in the example 1 Vol-%).

Fig. 45 Time-dependent calcite dissolution at 0.03 Vol% CO<sub>2</sub> (atmospheric pressure) and increased CO<sub>2</sub> partial pressure (1 Vol%)

Further examples can be found as already quoted in chapter 2.1.4.2 for K-feldspar, albite, calcite, pyrite, organic carbon and pyrolusite in the database PHREEQC.dat or WATEQ4F.dat within the keyword RATES. There, all parameters are marked as comments by means of the # sign in the block KINETICS.

In the following, an example for the definition of **pyrite weathering rates** is given:

## KINETICS

# example for KINETICS data block for pyrite

-tol 1e-8

# tolerance for Runge\_Kutta

-m0 5e-4

# initial amount of pyrite in mol

-m 5e-4

```

      -parms -5.0  0.1  .5  -0.11      # parameter in kinetics equation
#      parm(1) = log10(A/V) in 1/dm
#      parm(2) = exponent for (m/m0)
#      parm(3) = exponent for O2
#      parm(4) = exponent for H+
RATES
Pyrite
-start
  5 rem Pyrite weathering rates
  10 if (m <= 0) then goto 200          // m = mole of reactant *
  20 if (si("Pyrite") >= 0) then goto 200 // si = saturation index *
  20 rate = -10.19 + parm(1) \
  21   + parm(3)*lm("O2") \
  22   + parm(4)*lm("H+") \
  23   + parm(2)*log10(m/m0)           // parm(i) = parameter*
                                      // lm= log10 molality *
  30 moles = 10^rate * TIME           // time interval defined in steps*
  40 if (moles > m) then moles = m
  50 if (moles >= (mol("O2")/3.5)) then moles = mol("O2")/3.5
  200 save moles
-end

```

\* the `'''` included comments cannot appear like this in a PHREEQC-BASIC script because the BASIC interpreter is trying to interpret them. It is only possible to include commentary lines at the beginning of a line by means of REM (remark).

In order to write your own kinetics programs it is necessary to familiarize yourself with the programming language BASIC and particularly with the special BASIC-codes within PHREEQC.

#### 2.2.2.3.2. BASIC within PHREEQC

The BASIC interpreter, which comes along with the Linux operating system (Free Software Foundation, Inc.), is implemented in PHREEQC. It is e.g. used, as already demonstrated, for the integration of kinetic rates to determine converted quantities of substance in mol with respect to a given time. Therefore, a BASIC program for each kinetic reaction has to be ready either in the database (PHREEQC.dat, WATEQ4F.dat, etc.) or in the respective input file. Each programs stands for itself (no global variables) and lines have to be numbered consecutively (e.g. 10, 20, 30,...). The transfer of data between the BASIC programs and PHREEQC is done by using the command GET and PUT as well as the command TIME. The final result of a kinetic calculation is written back to PHREEQC by means of SAVE. Thereby, no rates but quantities of moles are transferred after each reaction. A positive sign indicates that concentrations of the reactant in solution have increased, a negative sign that they decreased.

The BASIC code can be used within the keyword RATES, but also for USER\_GRAPH, USER\_PRINT and USER-PUNCH and always occurs between the commands

-start

-end.

Table 27 presents a list of the standard commands within the BASIC interpreter of PHREEQC, Table 28 the special codes in BASIC of PHREEQC.

**Table 27 List of standard commands within the BASIC interpreter of PHREEQC (Parkhurst & Appelo 1999)**

+, -, *, /	Add, subtract, multiply, and divide
String1 + String2	String concatenation
a ^ b	Exponentiation
<, >, <=, >=, <>, =, AND, OR, XOR, NOT	Relational and Boolean operators
ABS(a)	Absolute value
ARCTAN(a)	Arctangent function
ASC(character)	ASCII value for character
CHR\$(number)	Convert ASCII value to character
COS(a)	Cosine function
DIM a(n)	Dimension an array
DATA list	List of data
EXP(a)	e <sup>a</sup>
FOR i = n TO m STEP k ..... NEXT I	“For” loop
GOTO line	Go to line number
GOSUB line	Go to subroutine
IF (expr) THEN statement ELSE statement	If, then, else statement (on one line; a ‘\’ may be used to concatenate lines)
INSTR("aab", "b")	returns the character position of substring within a string, 0 if not found
LEN(string)	Number of characters in <i>string</i>
LOG(a)	Natural logarithm
LOG10(a)	Base 10 logarithm
LTRIM(" ab")	trims white space from beginning of a string
MID\$(string, n)	Extract characters from position <i>n</i> to end of <i>string</i> .
MID\$(string, n, m)	Extract <i>m</i> characters from <i>string</i> starting at position <i>n</i> .
a MOD b	returns remainder a/b
ON expr GOTO line1, line2, ... ON expr GOSUB line1, line2, ...	If the expression's value, rounded to an integer, is <i>N</i> , go to the <i>N</i> th line number in the list. If <i>N</i> is less than one or greater than the number of line numbers listed, execution continues at the next statement after the ON statement
READ	Read from DATA statement
REM	At beginning of line, line is a remark with no effect on the calculations

RESTORE line	Set pointer to DATA statement of <i>line</i> for subsequent READ
RETURN	Return from subroutine
RTRIM("a ")	Trims white space from the end of a string
SGN(a)	Sign of <i>a</i> , +1 or -1
SIN(a)	Sine function
SQR(a)	$a^2$
SQRT(a)	$\sqrt{a}$
STR\$(a)	Convert number to a string
TAN(a)	Tangent function
TRIM("a ")	Trims white space from beginning and end of a string
VAL(string)	Convert string to number.
WEND	indicates the end of a "While" loop
WHILE (expression) ... WEND	"While" loop

**Table 28 Special codes in BASIC of PHREEQC**

ACT("HCO3-")	activity of an aqueous, exchange, or surface species
ALK	alkalinity of solution
CALC_VALUE("pCa")	evaluates a definition of calculated values
CELL_NO	cell number in TRANSPORT or ADVECTION calculations
CHANGE_POR(0.21, cell_no)	modifies the porosity of a cell
change_surf ("Hfo", 0.2, "Sorbedhfo", 0, cell_no)	changes the diffusion coefficient of a SURFACE and renames the SURFACE
CHARGE_BALANCE	aqueous charge balance in equivalents
DESCRIPTION	description of a solution
DIST	distance to midpoint of cell in TRANSPORT calculations, cell number in ADVECTION calculations, "-99" in all other calculations
EDL("Na", "Hfo")	The moles of an element or water in the diffuse layer, the charge (eq or C/m2) or the potential (V) of a surface
EQUI("Calcite")	Moles of a phase in the pure-phase (equilibrium-phase) assemblage
EXISTS(i1[, i2, ...])	Determines if a value has been stored with a PUT statement for the list of one or more subscripts. The function equals 1 if a value has been stored and 0 if no value has been stored. Values are stored in global storage with PUT and are accessible by any BASIC program. See description of PUT for more details.
GAS("CO2(g)")	Moles of a gas component in the gas phase

GET(i1[, i2, ...])	Retrieves the value that is identified by the list of one or more subscripts. Value is zero if PUT has not been used to store a value for the set of subscripts. Values stored in global storage with PUT are accessible by any BASIC program. See description of PUT for more details
GET_POR(cell_no)	Porosity in a cell
GRAPH_SY -la("H+"), -la("e-")	Plots variables on the secondary y-axis of the graph
GRAPH_X tot("Na")	Defines the x-axis of the graph (1 variable)
GRAPH_Y tot("Cl"), tot("K")	Plots variables on the y-axis of the graph
KIN("CH2O")	Moles of a kinetic reactant
LA("HCO3-")	Log10 of activity of an aqueous, exchange, or surface species
LK_NAMED("aa_13C")	Log10 of a K value in NAMED_EXPRESSIONS at the current temperature.
LK_PHASE("O2(g)")	Log10 of a K value in PHASES at the current temperature.
LK_SPECIES("OH-")	Log10 of a K value of a SOLUTION, EXCHANGE, or SURFACE_SPECIES at the current temperature.
LM("HCO3-")	Log10 of molality of an aqueous, exchange, or surface species
M	Current moles of reactant for which the rate is being calculated (see KINETICS)
M0	Initial moles of reactant for which the rate is being calculated (see KINETICS)
MISC1("Ca(x)Sr(1-x) SO4")	Mole fraction of component 2 at the beginning of the miscibility gap, returns 1.0 if there is no miscibility gap (see SOLID SOLUTIONS)
MISC2("Ca(x)Sr(1-x) SO4")	Mole fraction of component 2 at the end of the miscibility gap, returns 1.0 if there is no miscibility gap (see SOLID SOLUTIONS)
MOL("HCO3-")	Molality of an aqueous, exchange, or surface species
MU	Ionic strength of the solution (mol)
OSMOTIC	Returns the osmotic coefficient if the Pitzer model is used, or 0.0 if the ion-association model is used
PARM(i)	Parameter array defined in KINETICS data block
PERCENT_ERROR	Percent charge-balance error $[100(\text{cations} - \text{anions})/(\text{cations} + \text{anions})]$
PRINT	Write to output file
PUNCH	Write to selected-output file
PUT(x, i1[, i2, ...])	Saves value of x in global storage that is identified by a sequence of one or more subscripts. Value of

	$x$ can be retrieved with <code>GET(<i>i</i>1[, <i>i</i>2, ...])</code> and a set of subscripts can be tested to determine if a value has been stored with <code>EXISTS(<i>i</i>1[, <i>i</i>2, ...])</code> . <code>PUT</code> may be used in <code>RATES</code> , <code>USER_PRINT</code> , or <code>USER_PUNCH BASIC</code> programs to store a value. The value may be retrieved by any of these <code>BASIC</code> programs. The value persists until overwritten using a <code>PUT</code> statement with the same set of subscripts, or until the end of the run. For a <code>KINETICS</code> data block, the <code>BASIC</code> programs for the rate expressions are evaluated in the order in which they are defined in the input file.
RXN	Amount of reaction (moles) as defined in -steps in <code>REACTION</code> data block for a batch-reaction calculation, otherwise zero
S_S("MgCO3")	Current moles of a solid-solution component
SAVE	Last statement of <code>BASIC</code> program that returns the moles of kinetic reactant, counted positive when the solution concentration of the reactant increases
SI("Calcite")	Saturation index of a phase, $\text{Log}_{10} (IAP/K)$
SIM_NO	Simulation number, equals one more than the number of <code>END</code> statements before current simulation
SIM_TIME	Time (s) from the beginning of a kinetic batch-reaction or transport calculation
SR("Calcite")	Saturation ratio of a phase, $(IAP/K)$
STEP_NO	Step number in batch-reaction calculations, or shift number in <code>ADVECTION</code> and <code>TRANSPORT</code> calculations
SUM_GAS("{CO2, O2}", "O")	returns Summed moles of an element in gas-formulas listed in {...}. write the chemical formula in {...}, not the name of the gas in <code>PHASES</code>
SUM_S_S("CaCdCO3", "O")	Summed moles of an element in <code>SOLID SOLUTIONS</code> .
SUM_SPECIES("{OH-, NaOH}", "H")	returns Summed moles of an element in <code>SOLUTION</code> , <code>EXCHANGE</code> , and <code>SURFACE_SPECIES</code> listed in {..., ..., ...}.
SURF("As", "Hfo")	Moles of an element sorbed on a <code>SURFACE</code> .
SYS("Na")	Total moles of an element in all phases ( <code>SOLUTION</code> , <code>EQUILIBRIUM_PHASES</code> , <code>SURFACE</code> , <code>EXCHANGE</code> , <code>SOLID SOLUTIONS</code> , and <code>GAS_PHASE</code> )
TC	Temperature in Celsius
TIME	Time interval for which moles of reaction are calculated in rate programs, automatically set in the time-step algorithm of the numerical

	integration method
TK	Temperature in Kelvin
TOT("Fe(2)")	Total molality of element or element redox state. TOT("water") is total mass of water (kg)
TOTAL_TIME	Cumulative time (s) including all advective (for which <b>-time_step</b> is defined) and advective-dispersive transport simulations from the beginning of the run or from last <b>-initial_time</b> identifier

### 2.2.2.4 Introductory example for isotope fractionation

Isotopes can be modeled within PHREEQC easily in reverse modeling. Another option is to define an isotope in RATES and calculate the distribution of stable and radioactive isotopes via KINETICS (see example section 4.2.4 and Apello & Postma 2005). The most powerful option, however, is to define isotopes in a database via the keyword ISOTOPE which is possible since version 2.7 (2003).

PHREEQC can model the distribution of  $^2\text{H}$ ,  $^3\text{H}$  (tritium),  $^{18}\text{O}$ ,  $^{13}\text{C}$ ,  $^{14}\text{C}$ , and  $^{34}\text{S}$  of species and phases by using the database iso.dat. In the following, a clipping from a definition of SOLUTION\_MASTER\_SPECIES taken from iso.dat (Thorsten & Parkhurst 2002) is displayed:

#### SOLUTION\_MASTER\_SPECIES

```
~~~~~clipped~~~~~
C(4) CO2      0   HCO3
[13C] [13C]O2  0   13      13
[13C](4) [13C]O2  0   13
[14C] [14C]O2  0   14      14
[14C](4) [14C]O2  0   14
[18O] H2[18O]  0   18      18
D    D2O      0   2        2
T    HTO      0   3        3
S    SO4-2    0.0 SO4      31.972
~~~~~clipped~~~~~
```

#### ISOTOPE

```
H
  -isotope  D    permil 155.76e-6    # VSMOW (Clark & Fritz 1997)
  -isotope  T    TU    1e-18         # Solomon & Cook, in Cook &
                                     # Herczeg 2000
                                     # 1 THO in 10^18 H2O

C
  -isotope  [13C] permil 0.0111802    # VPDB, Vienna Pee Dee Belemnite
                                     # (Chang & Li 1990)
  -isotope  [14C] pmc   1.175887709e-12 # Mole fraction of 14C in Percent
                                     # Modern Carbon
```

```

# 13.56 Modern Carbon dpm (Kalin in
# Cook & Herczeg 2000)
C(4)
  -isotope [13C](4) permil 0.0111802 # VPDB, Vienna Pee Dee Belemnite
  # (Chang & Li 1990)
  ...-isotope [14C](4) pmc 1.175887709e-12 # Mole fraction of 14C in Percent
  # Modern Carbon
  # 13.56 Modern Carbon dpm (Kalin in
  # Cook & Herczeg 2000)

O
  -isotope [18O] permil 2005.2e-6 # VSMOW (Clark & Fritz 1997)
~~~~~clipped~~~~~

```

Furthermore, the ISOTOPE\_RATIOS, ISOTOPE\_ALPHAS, and fractionation factors have to be defined. An example for using NAMED\_EXPRESSION and CALCULATE\_VALUES in the database is given here:

#### NAMED\_EXPRESSIONS

# H2O fractionation factors

```

Log_alpha_D_H2O(l)/H2O(g) # 1000ln(alpha(25C)) = 76.4
# 0-100 C
-ln_alpha1000 52.612 0.0 -76.248e3 0.0 24.844e6
Log_alpha_T_H2O(l)/H2O(g) # 1000ln(alpha(25C)) = 152.7
# 0-100 C
-ln_alpha1000 105.224 0.0 -152.496e3 0.0 49.688e6
Log_alpha_18O_H2O(l)/H2O(g) # 1000ln(alpha(25C)) = 9.3
# 0-100 C
-ln_alpha1000 -2.0667 0.0 -0.4156e3 0.0 1.137e6
~~~~~clipped~~~~~

```

#### CALCULATE\_VALUES

```

R(13C)_CH4(aq)
-start
  10 ratio = -9999.999
  20 if (TOT("[13C]") <= 0) THEN GOTO 100
  30 total_13C = sum_species("{C,[13C]}{H,D}4","[13C]")
  40 total_C = sum_species("{C,[13C]}{H,D}4","C")
  50 if (total_C <= 0) THEN GOTO 100
  60 ratio = total_13C/total_C
  100 save ratio
-end
~~~~~clipped~~~~~

```

Finally, SOLUTION\_SPECIES have to be defined for all possible permutations as can see from this example:

# CO2 reactions

```

0.5CO2 + 0.5C[18O]2 = CO[18O]
log_k      0.301029995663 # log10(2)

```

```

[13C]O2 + C[18O]2 = [13C][18O]2 + CO2
log_k      0.0

0.5[13C]O2 + 0.5[13C][18O]2 = [13C]O[18O]
log_k      0.301029995663      # log10(2)

[14C]O2 + C[18O]2 = [14C][18O]2 + CO2
log_k      0.0

0.5[14C]O2 + 0.5[14C][18O]2 = [14C]O[18O]
log_k      0.301029995663      # log10(2)

CO2 + 2H2[18O] = C[18O]2 + 2H2O
-add_logk   Log_alpha_18O_CO2(aq)/H2O(l)      2.0
~~~~~clipped~~~~~

```

Adding even one isotope is thus a considerable effort and not advisable for an input file. The iso.dat comes with the distribution of PHREEQCI and will be automatically installed in the appropriate folder. However, iso.dat can also be used with the PHREEQC batch version and PHREEQC for Windows. To model the fractionation of  $^{13}\text{C}$  for the carbon species the following input file can be used. The standard output is turned off via PRINT and -reset false. By using the semicolon (instead of carriage return) consecutive lines are written in one line to make the file more compact. The results for  $^{14}\text{C}$ , tritium, deuterium, and  $^{18}\text{O}$  input are not used and explained in this example (4\_Isotope\_fractionation.phrq).

### 2.2.2.5 Introductory examples for reactive mass transport

#### 2.2.2.5.1. Simple 1D transport: column experiment

After equilibrium reactions and kinetically controlled reactions, the reactive mass transport will be described as a final introductory example (for theory see chapter 1.3). Within PHREEQC there are two options to simulate one-dimensional (1D) transport with constant velocity. Using the keyword **ADVECTION**, simple simulations can be carried out by a mixing cell approach. With the keyword **TRANSPORT** dispersion, diffusion and double porosity (mobile and immobile pores) can be taken into account. The units used are basically meter and seconds. One-dimensional modeling is well suited for simulating laboratory column experiments or to model processes in an aquifer along a theoretical flow path. Concerning the consideration of dilution processes during 1D-modeling in groundwater, see chapter 1.3.3.4.2.

The following example shows the result of a column experiment with an 8 m long column filled with a cation exchanger. Initially, the column was equilibrated with a solution containing 1 meq/L  $\text{NaNO}_3$  and 0.2 meq/L  $\text{KNO}_3$ , i.e. the conditioning solution was applied until the composition determined at the inlet of the column equaled that at the outlet. Then, the input solution was changed to a 0.5 meq/L  $\text{CaCl}_2$  solution. The concentrations monitored at the outlet can be seen in Fig. 48. The time scale on the x-axis starts at 0, the time when the input solutions were changed. The x-axis is scaled in water volumes and represents a threefold exchange of the water within the column (shift = 120).

**Fig. 48 Laboratory column experiment: changes in chloride, sodium, potassium, and calcium concentrations at the column’s outlet; 40 “shifts” correspond to a complete exchange of the water volume within the column**

Chloride behaves like an ideal tracer and is only affected by dispersion. Calcium is not detected in solution after the first exchange of all the water in the column (shift = 40) as it is exchanged for sodium and potassium. After all sodium is removed from the exchanger, calcium can only exchange for potassium. Because calcium ions have two positive charges while potassium has only one, each calcium ion removes two potassium ions which leads to a peak in the potassium-concentrations. Only after the water in the column has been exchanged about 2.5 times, the calcium is detected at the outlet.

In the following the PHREEQC job is shown that simulates the experiment (5a\_Transport-column-experiment.phrq). To adjust the model to the data observed, the exchange capacity (X under EXCHANGE, here 0.0015 mol per kg water), the selectivity coefficients in the database WATEQ4F.dat and the chosen dispersivity (TRANSPORT, dispersivity, here 0.1 m) are decisive besides the spatial discretisation (number of cells, here 40). Changing the dispersivity to a very small value (e.g.  $1 \cdot 10^{-6}$ ), no numerical dispersion occurs which shows that numerical stability criteria are fulfilled.

It is important to notice that the same solution is defined by default for all 40 cells of the column at the beginning of the job (SOLUTION 1-40). If additionally kinetics and equilibrium reactions are taken into account, the same applies for the keywords KINETICS and EQUILIBRIUM\_PHASES. Writing KINETICS 1 instead of KINETICS 1-40, the kinetic reaction would only be taken into account for cell 1. The syntax of the keyword TRANSPORT is explained in detail in Table 29.

**Table 29 Syntax of the keyword TRANSPORT in PHREEQC (Parkhurst & Appelo 1999)**

Keyword	example	default	comments
-cells	5	0	Number of cells in a 1D column to be used in the advective-dispersive transport simulation
-shifts	25	1	number of advective shifts or time steps, which is the number of times the solution in each cell will be shifted to the next higher or lower numbered cell; the total time simulated is <i>shifts</i> * <i>time_step</i>
-time_step	3.15e7	0	Time, in seconds, associated with each shift or diffusion period
-flow_direction	forward	forward	forward, back, or diffusion_only
-boundary_conditions	flux constant	flux flux	constant, closed, flux for first cell and last cell
-lengths	4*1.0 2.0	1	Length of each cell (m). Any number of <i>lengths</i> up to the total number of cells ( <i>cells</i> ) may be entered
-dispersivities	4*0.1 0.2	0	Dispersivity assigned to each cell (m). Any number of <i>dispersivities</i> up to the total number of cells ( <i>cells</i> ) may be entered.
-correct_disp	true	true	true or false: When <i>true</i> , dispersivity is multiplied with $(1 + 1/cells)$ for column ends with flux boundary conditions. This correction is recommended when modeling effluent composition from column experiments.
-diffusion_coefficient	1.0e-9	0.3e-9	Diffusion coefficient in m <sup>2</sup> /s
-stagnant	1 6.8e-6 0.3 0.1 5	0 0 0 0	Defines the maximum number of stagnant (immobile) cells associated with each cell in which advection occurs (mobile cell). The immobile cells are usually defined to be a 1D column that is connected to the mobile cell; however, the connections among the immobile cells may be defined arbitrarily with <b>MIX</b> data blocks. Each immobile cell that is used must have a defined solution and either a <b>MIX</b> data block must be defined or, for the first-order exchange model, the <i>exchange_factor</i> must be defined, for details refer to manual
-thermal_diffusion	3.0 0.5e-6	2 1e-6	temperature-retardation-factor and thermal diffusion coefficient; for details refer to manual
-initial_time	1000	cumulative time	Time (seconds) at the beginning of the transport simulation. The identifier sets the initial value of the variable controlled by <b>-time</b> in the <b>SELECTED_OUTPUT</b> data block.
-print_cells	1-3 5	1-n	Identifier to select cells for which results will be written to the output file.

Keyword	example	default	comments
-print_frequency	5	1	Identifier to select shifts for which results will be written to the output file.
-punch_cells	2-5	1-n	Identifier to select cells for which results will be written to the selected-output file.
-punch_frequency	5	1	Identifier to select shifts for which results will be written to the selected-output file.
-dump	dump.file	phreeqc.dmp	Identifier to write complete state of advective-dispersive transport simulation after every <i>dump_modulus</i> advection shifts or diffusion periods. The file is formatted as an input file that can be used to restart calculations.
-dump_frequency	10	shifts/2 or 1	Complete state of a advective-dispersive transport simulation will be written to dump file after <i>dump_modulus</i> advection shifts or diffusion periods.
-dump_restart	20	1	Starting shift number for the calculations, if restarting from a dump file. The shift number is written in the dump file by PHREEQC. It equals the shift number at which the dump file was created
-warnings	false	true	If true, warning messages are printed to the screen and the output file

#### 2.2.2.5.2. 1D transport, dilution, and surface complexation in an abandoned uranium mine

A second, more complex 1D reactive transport example is demonstrated with the input file (5b\_Transport\_mine\_dilution.phrq). It is a simplified version of a model to predict what happens when a uranium mine is closed down with no action taken. Since the mine was an in-situ leaching mine it contains huge amounts of sulfuric acid leading to a composition of the mine drainage as described in SOLUTION 0. Furthermore, it was assumed that some calcite and pyrite is available in the downstream aquifer which will control the sulfate concentrations due to precipitation of gypsum. Since oxygen is available as well pyrite will be oxidized. To be realistic in terms of reaction kinetics, the pyrite oxidation was modeled via KINETICS and RATES. The subsequent precipitation of  $\text{Fe}(\text{OH})_3$  is assumed to be fast and was therefore modeled by the thermodynamic approach (EQUILIBRIUM\_PHASE). By checking the saturation indices it becomes obvious that no uranium mineral is oversaturated and thus able to control the uranium concentrations in the groundwater. Thus, as long as we assume that no redox processes occur (e.g. decay of organic matter reducing the redox potential) only surface complexation of uranium on ironhydroxide (formed from pyrite weathering) can limit the uranium concentration in the downstream area. Another important aspect is the dilution of the contaminant (see chapter 1.3.3.4.2) which was solved via the MIX statements by mixing increasing shares of groundwater with increasing distance from the source of contamination.

A look at the input file 5b\_Transport\_mine\_dilution.phrq shows that it makes intensive use of the semicolon as an equivalent for carriage return (new line) in order to make the file as compact as possible. Further the definition of the SURFACE and the MIX statements are disabled by “#” (marked in *italic*). By removing the “#” in front of the respective statement blocks this option can be easily switched on and off which produces very different results as can be seen from Fig. 49 to Fig. 52 (screen shots from the PHREEQC for Windows Chart option).

**Fig. 49** Uranium breakthrough according to 1D transport simulation taking into account neither dilution nor surface complexation on ironhydroxides; concentrations were plotted every 4 years; no retardation with respect to groundwater flow (20 m/year) can be seen.

**Fig. 50** Uranium breakthrough according to 1D transport simulation taking into account surface complexation on ironhydroxides but no dilution; concentrations were plotted every 4 years; the uranium concentrations are reduced to about 50%, however, this value depends significantly on the assumptions for ironhydroxide surface area and pyrite oxidation rate.

**Fig. 51** Profile through downstream area of mine with dilution but no surface complexation of uranium on ironhydroxides

**Fig. 52 Profile through downstream area of mine with dilution and surface complexation of uranium on ironhydroxides**

Dilution and surface complexation are in this case the dominant factors for natural attenuation, however, in particular the way of assuming mixing ratios in this example is straight forward but not in all cases sufficient. This main disadvantage of any 1D simulation along a stream path can be overcome only by means of a 2D or 3D model. How this can be done by means of PHAST will be demonstrated with the next and last introductory example of this chapter.

#### 2.2.2.5.3. 3D transport with PHAST

The restriction of PHREEQC with respect to reactive transport modeling to 1D is overcome by PHAST (Parkhurst et al. 2004). Simulation of flow and transport are based on HST3D (Kipp 1997), a 3D flow and transport finite difference code for steady state and transient conditions. Within PHAST the HST3D code is restricted to constant fluid density and constant temperature. PHREEQC is embedded in PHAST offering many of PHREEQC's options of geochemical reactions (EQUILIBRIUM\_PHASES, EXCHANGE, SURFACE, GAS\_PHASE, SOLID\_SOLUTIONS, KINETICS). The keyword "REACTIONS" is not available within PHAST. Flow, transport, and geochemical reactions are treated as separate processes without feedback from each other. Thus, e.g. precipitation of a mineral does not affect the hydraulic permeability or flow and transport simulation.

Two graphical user interfaces (GUI) are available: GoPhast and WPhast. Both can be downloaded as well as PHAST from the USGS web page ([http://www.brr.cr.usgs.gov/projects/GWC\\_coupled/phast/index.html](http://www.brr.cr.usgs.gov/projects/GWC_coupled/phast/index.html)). The recent version of PHAST and WPhast (as of the date of printing) are included on

the CD of this textbook, however, it is recommended to download the most recent software. Independent from the GUI chosen PHAST has to be installed separately and it is highly recommended to install the programs according to the default settings. Following we will refer to the use of WPhast as GUI für PHAST since it offers a professional graphical user interface for setting up the 3D flow model. PHAST offers 3 output formats:

1. suitable for viewing with any text editor
2. suitable for exporting to spreadsheets
3. binary, hierarchical data format (HDF)

With the installation of PHAST two software tools will be installed as well: PHASTHDF and ModelViewer. The utility program PHASTHDF is used to extract HDF files into a text format. The ModelViever utility program can be used to display the results from h5 files.

The following sequences of screen shots (Fig. 53) show how easy a new reactive transport model can be set up with WPhast. The information will be saved in a file with the extension **.wphast** (e.g. mine\_isl.wphast).

Not included in this GUI is the definition of the chemical part of the model. This has to be done separately e.g. by means of PHREEQC for Windows or any text editor. The name of the PHREEQC input file must be identical with the PHAST project name with the extension **.chem.dat** (e.g. TEST.chem.dat). Furthermore, both files have to be in the same folder (5c\_Transport\_PHAST) together with a third file named phast.dat. By installing WPhast a file phast.dat is supplied which is a renamed phreec.dat. However, any valid PHREEQC data file can be renamed to phast.dat and copied into the project folder. The PHREEQC input file has to define at least one solution and may contain the keywords EQUILIBRIUM\_PHASES, SURFACE, EXCHANGE, GAS\_PHASE, KINETICS, and SOLID\_SOLUTIONS.

Additionally, the PHREEQC input file must define the output of results by means of the keywords SELECTED\_OUTPUT and USER\_PUNCH. Nothing is printed to the file with the extension .dummy.sel. However, the statement is obligatory for the printing of the results to the file with the extension .xyz.chem. The frequency of printing is defined in WPhast through the properties menu and Print Frequency.

END

To run the 3D model for the uranium contamination from the in-situ leaching mine you have to install WPhast from the CD or the Internet and copy the folder WPhast\_example to your hard disk. This folder contains the files mine\_isl.wphast, phast.dat, and mine\_isl.chem.dat. Part of the confined aquifer downstream was discretized with 30 columns (x), 20 rows (y) and 2 layers (z). The hydraulic conductivity was set uniform to  $2 \cdot 10^{-6}$  m/s in x and y ( $2 \cdot 10^{-7}$  m/s for z). Longitudinal dispersivity was assumed to be 100 m and 5 m for the vertical and horizontal dispersivity. As can be seen from Fig. 54 the 3D model can be viewed in top view or as 3D image.

Running PHAST may take considerable time since PHREEQC is called for each cell and time step. In the example given the number of cells is 30 x 20 x 2. Each of the 1200 cells is called 30 times (36,000 PHREEQC calls).

With Tools/Data the user can chose the parameter (pH,  $E_H$ , As, U,  $SO_4$ , Head, etc.) to be displayed. Using Mine\_isl.xyz.chem any contourline program (e.g. Surfer) or GeoInformationSystem (GIS) can be used to plot the data according to the time steps defined and selected in WPhast (Fig. 56, Uranium concentrations in  $\mu\text{g/L}$ ).

**Fig. 56** Map of uranium concentrations [ $\mu\text{g/L}$ ] downstream of the in-situ leaching mine after 30 years

### 3 Exercises

The following chapter contains several exercises from simple modeling of equilibrium reactions (chapter 3.1) to more advanced options like kinetics (chapter 3.2) and reactive mass transport (chapter 3.3). The solutions of all exercises are explained in detail in chapter 4. All exercises have been modeled with PHREEQC version 2.14.03. This latest version (as of the time of book printing) can be found on the enclosed CD (with different installation versions for Windows, Mac or Unix workstations). The input files of each exercise are also enclosed on the CD (folder PhreeqC\_files).

For users who want to define their own modeling the suggestion is to use an existing input file, keep the input file structure and modify only the respective data. Individual keywords are used in the following examples (SOLUTION, TITLE and END are not considered as they are used in all examples):

ISOTOPES	exercise intro 4
----------	------------------

Beyond the examples presented in this book, users can also do more exercises using the 18 examples that are automatically installed with the installation of the PHREEQC program in the folder “Examples”. They include:

Example 1.--Speciation calculation

Example 2.--Equilibration with pure phases

Example 3.--Mixing

Example 4.--Evaporation and homogeneous redox reactions

Example 5.--Irreversible reactions

Example 6.--Reaction-path calculations

Example 7.--Gas-phase calculations

Example 8.--Surface complexation

Example 9.--Kinetic oxidation of dissolved ferrous iron with oxygen

Example 10.--Aragonite-strontianite solid solution

Example 11.--Transport and cation exchange

Example 12.--Advective and diffusive flux of heat and solutes

Example 13.--1D transport in a dual porosity column with cation exchange

Example 14.--Advective transport, cation exchange, surface complexation, and mineral equilibria

Example 15.--1D Transport: Kinetic biodegradation, cell growth, and sorption

Example 16.--Inverse modeling of Sierra spring waters

Example 17.--Inverse modeling with evaporation

Example 18.--Inverse modeling of the Madison aquifer

A detailed description of the solutions for these examples can be found in the PHREEQC manual (Parkhurst & Appelo 1999).

### 3.1 Equilibrium reactions

#### 3.1.1 Groundwater – Lithosphere

##### 3.1.1.1 Standard output well analysis

The following hydrogeochemical analysis (Table 30) is given for the drinking water well (“B3”) in the model area shown in Fig. 57 (concentrations in mg/L):

**Table 30** Hydrogeochemical analysis of the drinking water well B3 from Fig. 57

Temperature = 22.3°C	pH = 6.7	pE = 6.9	
Ca = 75.0	Mg = 40.0	K = 3.0	Na = 19.0
HCO <sub>3</sub> <sup>-</sup> = 240.0	SO <sub>4</sub> <sup>2-</sup> = 200.0	Cl <sup>-</sup> = 6.0	NO <sub>3</sub> <sup>-</sup> = 1.5
NO <sub>2</sub> <sup>-</sup> = 0.05	PO <sub>4</sub> <sup>3-</sup> = 0.60	SiO <sub>2</sub> = 21.59	F <sup>-</sup> = 1.30
Li = 0.030L	B = 0.030	Al = 0.056	Mn = 0.014
Fe = 0.067	Ni = 0.026	Cu = 0.078	Zn = 0.168
Cd = 0.0004	As = 0.005	Se = 0.006	Sr = 2.979
Ba = 0.065	Pb = 0.009	U = 0.003	

**Fig. 57** Model area for exercises in the chapters 3.1.1.1 - 3.1.1.8, chapter 3.1.4.2, chapters 3.1.5.2 - 3.1.5.5

How would you interpret the analysis? Have a close look at the redox-sensitive elements (which elements do not fit in the general scheme and why?). Plot the species distribution of the Ca-, Mg-, Pb- and Zn-species in the form of a pie chart

(what is remarkable?). Illustrate the supersaturated Fe- and Al-mineral phases in two bar charts.

### **3.1.1.2 Equilibrium reaction – solubility of gypsum**

The town council plans to drill a new well for drinking water supply. From a logistic point of view (lengths of water pipes), it should be closer to the town than the present drinking water well B3. The new, planned location can be found as “B2” in Fig. 57. Is the planned location advisable from a hydrogeochemical point of view? Assume that the general groundwater flow direction is from the East to the West. Furthermore, consider the analysis of the drinking water well B3 as representative for the aquifer east of B2. Point out changes in the water chemistry and take into account drinking water standards when drawing a final conclusion.

### **3.1.1.3 Disequilibrium reaction – solubility of gypsum**

How does the water quality change when assuming that the retention time in the underground is so short that only a 50 %-saturation with regard to the predominant mineral phase will occur? (*Note: Using the keyword EQUILIBRIUM\_PHASES, it is not only possible to specify equilibria, but to determine defined disequilibria with the help of the saturation index as well. A saturation of 80% (undersaturation) would mean e.g.:  $IAP/KT = 80\% = 0.8$ ;  $\log IAP/KT = SI = \log 0.8 \approx -0.1$ ; see also Eq.35).*)

### **3.1.1.4 Temperature dependency of gypsum solubility in well water**

Data of more recent drilling holes show a certain geothermal influence in the area of B2. How would different temperatures in the underground affect the water quality in the planned well B2 (simulation range 10, 20, 30, 40, 50, 60, 70°C with a saturation of 50 %)? [*keyword REACTION\_TEMPERATURE*]

### **3.1.1.5 Temperature dependency of gypsum solubility in pure water**

Only for comparison: How much gypsum will be solved in distilled water at the same temperatures? How can the difference be explained in comparison to the well water?

### **3.1.1.6 Temperature- and $P(\text{CO}_2)$ -dependent calcite solubility**

In the well B3, seasonally changing amounts of calcium have been measured. This phenomenon is ascribed to karst weathering, which is not only dependent on temperature but also on the  $\text{CO}_2$  partial pressure in the soil (often increased  $\text{CO}_2$

concentrations in the soil are a product of microbial decomposition reactions). Simulate the theoretical solubility of calcite for a whole year with temperatures on winter days of 0 °C and a low CO<sub>2</sub> partial pressure (corresponding to the value of the atmosphere) up to temperatures of 40 °C and a high bioproductivity (P(CO<sub>2</sub>) = 10 Vol%) during summer times.

The following pairs of temperature and CO<sub>2</sub> partial pressure are given:

Temp.(°C)	0	5	8	15	25	30	40
CO <sub>2</sub> (Vol%)	0.03	0.5	0.9	2	4.5	7	10

Where is the maximum of karst weathering (tabular and graphic illustration) and why?

[Note: Gas phases can be put into equilibrium like mineral phases. Instead of SI use the gas partial pressure  $p$ : Convert CO<sub>2</sub> Vol% into [bar] and form the logarithm; e.g. 3 Vol% = 0.03 bar = -1.523 P(CO<sub>2</sub>).]

### 3.1.1.7 Calcite precipitation and dolomite dissolution

What happens when not only pure calcium carbonate (calcite) but also magnesium calcium carbonate (dolomite) exists? Present your results graphically. How is this kind of reaction called? [For simulation use mineral phase dolomite(d) = dispersive distributed dolomite]

### 3.1.1.8 Calcite solubility in an open and a closed system

While simulating the two previous exercises 3.1.1.6 and 3.1.1.7 you always assumed that the amount of CO<sub>2</sub> was unlimited. Such systems are called “open systems”. In reality, this is very rare. Usually, there is only a restrained amount of gas available (closed system).

Simulate for the drinking water well B3 the solution of calcite for an open and a closed system using a temperature of 15 °C and partial pressures of 2 and 20 Vol% respectively. Where is the difference between the two systems? What changes with increasing partial pressure and why? Consider, besides the solution of calcite, changes in pH values, too.

[Note: closed system: keyword GAS\_PHASE; here, the following parameters have to be defined: the total pressure = 1 bar, the volume = 1 L gas per L water, and the temperature of the gas = 35 °C; additionally: which gas is being used (CO<sub>2</sub>) and which partial pressure exists (here not the log P(CO<sub>2</sub>) is used like in EQUILIBRIUM\_PHASES, but the CO<sub>2</sub> partial pressure in bars!)]

### 3.1.1.9 Pyrite weathering

Many reactions are so slow that it is impossible to describe them using equilibrium reactions (e.g. the weathering of quartz, or pyrite in the absence of microorganisms). However, it is often interesting to figure out to what extent these

slow transformations affect the pH value or other (equilibrium) reactions in solution.

For mine flooding oxidation and reduction processes are of great importance. Due to the supply of oxygen, protons and sulfate are formed changing the chemistry of groundwater fundamentally, e.g. triggering the mobilisation of metals as a result of decreasing pH (“acidification”).

Model the oxidation of pyrite assuming exposure of the groundwater given in Table 31 to different quantities of oxygen (0.0, 0.001, 0.005, 0.01, 0.05, 0.1, 0.3, 0.6, 1.0 mol). Plot the changes for the two major elements resulting from pyrite dissolution as well as for the pH value.

**Table 31** Water analysis of a groundwater (concentrations in mg/L).

pH	6.5		
Redox potential	-120 mV	Al	0.26
Temperature	10.7 °C	SiO <sub>2</sub>	24.68
O <sub>2</sub>	0.49	Cl	12.76
Ca	64.13	HCO <sub>3</sub>	259.93
Mg	12.16	SO <sub>4</sub>	16.67
Na	20.55	H <sub>2</sub> S	2.33
K	2.69	NO <sub>3</sub>	14.67
Fe	0.248	NH <sub>4</sub>	0.35
Mn	0.06	NO <sub>2</sub>	0.001

*[Note: The keyword for the addition of definite amounts of a reactant to a solution is REACTION. The command SELECTED\_OUTPUT, which has already been mentioned in chapter 2.2.1.4, is very useful here. It directly displays all required data in an extra file (.csv) in a spreadsheet format, so that the user does not have to look through the whole output manually. Under “molalities” and under “totals” the species of interest and the total concentration of an element can be defined, respectively.]*

Additionally, show if it is possible to attenuate the reactions when adding calcium carbonate. Add U<sub>3</sub>O<sub>8</sub>(c) as a mineral phase and test if a diminution in the concentration of uranium can be observed when adding calcium carbonate.

*[It is worthwhile remarking that many of these slow reactions do not proceed linearly and therefore they can only be modeled to a first approximation. The weathering of pyrite, e.g., will be catalyzed by microbes which are subject to exponential growth. Such kinetics is considered in chapter 3.2.1.]*

### 3.1.2 Atmosphere – Groundwater – Lithosphere

#### 3.1.2.1 Precipitation under the influence of soil CO<sub>2</sub>

Considerable amounts of carbon dioxide are produced in the soil as a result of microbial degradation. Particularly during the summer, concentrations of CO<sub>2</sub> soil

gas can reach approximately 1-5 Vol% in a humid climate. This amount is a significant increase compared to the  $\text{CO}_2$  partial pressure in the atmosphere of 0.03 Vol% (see also the exercise in chapter 3.1.1.6). Simulate the effect that a soil  $\text{CO}_2$  partial pressure of 1 Vol% has on the following rainwater: Na = 8, K = 7, Ca = 90, Mg = 29,  $\text{SO}_4^{2-}$  = 82,  $\text{NO}_3^-$  = 80, C(+4) = 13 and Cl = 23 [all units in  $\mu\text{mol/L}$ ]. Value of pH: 5.1, temperature: 21°C.

*Attention: In PHREEQC, C(+4) has indeed to be expressed as C(+4) and not as alkalinity as we did it so far. Because of the low concentrations in rainwater, a “conventional” determination of the alkalinity by titration is not possible, only the determination of the TIC (total inorganic carbon, C(+4)) can be done.*

### 3.1.2.2 Buffering systems in the soil

How do different buffer systems in the soil (Al-hydroxide-, exchanger- (50 % NaX, 30 %  $\text{CaX}_2$ , 20 %  $\text{MgX}_2$ ), carbonate-, Fe-hydroxide-, Mn-hydroxide buffer) affect the chemical composition of the rainwater of the previous exercise (chapter 3.1.2.1) upon infiltration ( $\text{CO}_2$  partial pressure 1 Vol%)?

*[For modeling the exchanger buffer use the keyword EXCHANGE and then define the exchanger species and their respective amounts (e.g. NaX 0.5).]*

### 3.1.2.3 Mineral precipitates at hot sulfur springs

The following analysis of a sulfur-rich thermal water is given (Table 32):

**Table 32 Water analysis of a sulfur-rich thermal water (concentration in mol/L)**

pH	4.317	pe	-1.407	Temperature	75°C
B	2.506e-03	Ba	8.768e-08	C	1.328e-02
Ca	7.987e-04	Cl	5.024e-02	Cs	9.438e-06
K	3.696e-03	Li	1.193e-03	Mg	2.064e-06
Na	4.509e-02	Rb	1.620e-05	S	8.660e-03
Si	7.299e-03	Sr	3.550e-06		

Model what happens when this water discharges at a spring outlet and comes into contact with atmospheric oxygen and  $\text{CO}_2$ . Take into account that the diffusion of gas in water proceeds relatively quickly but that the contact with oxygen results in redox reactions of much slower kinetics. Therefore, restrict the addition of oxygen with the help of the keyword REACTION. Starting from 1 mg  $\text{O}_2/\text{L}$  add increasing concentrations up to the maximum amount of  $\text{O}_2$  that can be dissolved assuming that the water close to the spring cools down to 45 °C (gas solubility decreases with increasing temperature, see chapter 1.1.3.1).

*[Hint: Table 33 presents the  $\text{O}_2$  gas solubility in  $\text{cm}^3$  per  $\text{cm}^3$  water at a partial pressure of 100 Vol%]:*

**Table 33** Dependency of  $O_2$  solubility on temperature at  $P(O_2) = 100 \%$ 

Temperature	Gas solubility	Temperature	Gas solubility	Temperature	Gas solubility
0	0.0473	20	0.0300	50	0.0204
5	0.0415	25	0.0275	60	0.0190
10	0.0368	30	0.0250	70	0.0181
15	0.0330	40	0.0225	90	0.0172

*Estimate from Table 33 how much  $O_2$  per liter water is dissolved at the given temperature and at an atmospheric  $O_2$  partial pressure. For this approximation it can further be assumed that there is 1 mole  $O_2$  in 22.4 liter gas.]*

### 3.1.2.4 Formation of stalactites in karst caves

The rainwater of exercise chapter 3.1.2.1 infiltrates in a karst area. There is enough time that an equilibrium regarding the predominant mineral phase and an elevated  $CO_2$  partial pressure of 3 Vol% can be reached.

**Fig. 58** Formation of stalactites in karst caverns

In the underground, there is a karst cavern with an extension of 10 m length, 10 m width, and 3 m height connected via a natural tunnel to the atmosphere.

Approximately 100 liter of the infiltrated, calcareous water is dripping daily from the ceiling into the cavern, in which the  $\text{CO}_2$  partial pressure is the same as in the atmosphere. Stalactites form (Fig. 58) - why and in which amount per year?

How many mm per year do the stalactites grow assuming that the density of calcite is  $2.71 \text{ g/cm}^3$  and that approximately 15 % of the cavern ceiling is covered with stalactites?

### 3.1.2.5 Evaporation

Evaporation changes the rainwater chemistry in the sense of a relative depletion of volatile components and a relative enrichment of non-volatile components.

As the calculation of the evaporation is quite tricky in PHREEQC, the following example is given as an introduction. It is important to know that 1 kg of water consists of approximately 55.5 mol of  $\text{H}_2\text{O}$ . First, a titration with a negative amount of water (in mol) will be done, in order to remove pure water. Afterwards, the resulting, enriched solution has to be reconverted to 55.5 mol by mixing the solution with itself.

Title 90 % evaporation as example

Solution 1 rainwater

```
.....
REACTION 1          # evaporation
H2O    -1.0          # remove water by -H2O!
        49.95 moles  #90 % evaporation; 100% = 1 kg H2O = 55.5 mol =>
                        #90% = 49.95 mol
                        #the resulting 10 % of the original amount of water
                        #have the same chemical composition as the 100 %
                        #before => the same amount of substance in less
                        #solvent, i.e. enrichment has taken place
```

save solution 2

END

MIX

```
2      10           # mix SOLUTION 2 10 times with itself
                        # to get back to 100 % of enriched solution
```

save solution 3

END

....further reactions, e.g. equilibrium reactions etc.

Calculate the composition of seepage water with and without considering evaporation assuming that the annual average precipitation in an area is 250 mm, the current evaporation is 225 mm, and the surface runoff is 20 mm. Use the rainwater analysis of exercise chapter 3.1.2.1. Furthermore, there is an increased  $\text{CO}_2$  partial pressure of 0.01 bar in the unsaturated zone. This unsaturated zone consists mainly of limestone and sandstone.

Calculate the amount of calcite being dissolved every year in an area of  $50 \text{ km} \cdot 30 \text{ km}$ . How large is the volume of cavities created by this kind of karst weathering assuming a density of calcite of  $2.71 \text{ g/cm}^3$ ? How much is the theoretical subsidence resulting from the calcite dissolution per year over the whole area of  $50 \text{ km} \cdot 30 \text{ km}$ ? (Formation of caverns first prevents an immediate subsidence. Only after those caverns collapse, site-specific subsidence structures appear at the surface. This aspect of time and spatial distribution shall be neglected for the calculations above.)

### 3.1.3 Groundwater

#### 3.1.3.1 The pE-pH diagram for the system iron

In chapter 1.1.5.2.3, using the system  $\text{Fe-O}_2\text{-H}_2\text{O}$  as an example, it was demonstrated that the species distribution can be determined analytically under different pH- and redox conditions and illustrated in a pE-pH-diagram. In the following examples, the numerical solution will be modeled with the help of PHREEQC.

The modeling is relatively simple. In the input file, certain pE- and pH values have to be defined besides the species in solution. After the modeling, the dominant species (i.e. the species with the highest concentration) has to be determined from the species distribution in the output. Varying the pH value between e.g. 0 (acid) and 14 (alkaline) as well as the pE value between e.g. -10 (reducing) and +20 (oxidizing) and listing the dominant species for each pE-pH combination creates a pE-pH-diagram as a raster image. The smaller the increment (=step width) for the variation of pE and pH is chosen, the finer the raster of the pE-pH-diagram will be.

To avoid entering every pE and pH combination individually (e.g.: using an increment of 1 for pH and pE there would be 15 pH values  $\times$  31 pE values = 465 combinations!), a BASIC program was written. It copies a PHREEQC master input file, in which the job is defined for any pE and pH value once, and changes pE and pH step by step. The program is enclosed on the CD to this book ("ph\_pe\_diagramm.exe"). The program is asking for pH and pE minimum values, maximum values, and the increment ("delta"). Furthermore, the existing PHREEQC master input file and a new output file have to be chosen.

The program takes into account that aquatic species are limited in every pE-pH-diagram by the stability field of water. Therefore, the program deletes automatically all pE-pH combinations above the line of transformation  $\text{O}_2\text{-H}_2\text{O}$  or below the line of transformation  $\text{H}_2\text{O-H}_2$ . Assistance for the program can be found within the menu HELP.

When considering the increment of 1 for pE and pH, i.e. 15 pH values  $\cdot$  31 pE values, the output file would comprise 465 jobs, numbered from SOLUTION 1 to SOLUTION 465, each containing different pE- and pH values. In fact, there will be only 311 jobs since the SOLUTIONs with pE-pH values above or below the

stability field of water are missing. The water constituents defined under SOLUTION (e.g. Fe, Ca, Cl, C, S, etc.) are alike in all 311 jobs.

To avoid looking for the predominant species in 311 output jobs manually after modeling, two means are offered: At first, a `SELECTED_OUTPUT` (see also chapter 2.2.1.4) has to be defined in the PHREEQC master input file. Besides pE and pH, it will list all species of interest, for example all Fe species, in a .csv file. These species have to be specified explicitly under the sub keyword “-molalities”, e.g.  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$ ,  $\text{FeOH}^+$ , etc. The BASIC-reproduction program inserts the 311 SOLUTION jobs before the keyword `SELECTED_OUTPUT`. Since the SOLUTIONs are not separated by an `END`, one `SELECTED_OUTPUT` will be created for all SOLUTIONs displaying for each of the 311 jobs a row with the columns pH, pE, `m_Fe2+` (concentration of  $\text{Fe}^{2+}$  in mol/L), `m_Fe3+`, `m_FeOH+`, etc.

To open and to view this .csv file use GRID in PHREEQC. The species with the highest concentration (predominant species) have to be determined for each row (i.e. for each pE-pH combination). To avoid doing this manually, the data have to be copied into EXCEL and to be treated with a macro, which can also be found on the CD enclosed in this book. The macro can be activated by opening the Excel file “macro.xls” from the book’s CD and by clicking on “activate macros”. Now, one can either copy data instead of the given test data into table 1 or open the .csv file directly in Excel. The activated macro is available for all open Excel files. The macro itself can be opened under menu Extras/Macro/Macros under the name “maxwert”. Using the menu “edit”, the macro can be viewed and edited. The data range as well as the number of rows and columns for the data range has to be defined under “edit”. The definition for the test data follows:

Sub maxvalue

‘ adjust N% and M% as well as the data range

N% = **6**; M% = **4** ‘ N% = number of rows, M% = number of columns

Dim name As Range

Dim wert As Range

Set name = Worksheets(**“Table1”**).Range(**“A1:D1”**)

Set wert = Worksheets(**“Table1”**).Range(**“A1:D6”**)

The values marked in bold have to be changed according to the current data range. If data has been pasted into table 1 replacing the test data, the name of the worksheet needs no further modification. If the .csv file has been opened directly, the name of the current worksheet has to be entered in the macro.

The macro is started using the play button (▶) or the menu Execute/Execute SubUserForm. Then the macro automatically scans each row for the cell with the highest value (= the highest concentration). The columns pH and pE are skipped automatically. For each cell found with a maximum value the respective header cell is written into the first empty row right next to the defined data range. The completed EXCEL table finally has one column more than the original .csv file, in which the names of the predominant species for each pE-pH combination are given (Attention: If the data range has been defined too small by mistake, the

program will overwrite a column of the original data!). Note: The macro neither closes automatically nor displays the end of the calculation. The calculation will be finished after approximately 5 seconds at the most. After that, the Microsoft Visual BASIC window has to be closed manually to go back to the modified EXCEL table.

With the 3 columns pE, pH, and predominant species, a pE-pH-diagram can be generated as a raster image in Excel. The first step is to sort all three columns according to the column “predominant species” (menu Data/Sorting). The most suitable diagram type is scatter plot (XY) with  $X = \text{pH}$  and  $Y = \text{pE}$ . When highlighting the columns pE and pH and creating a scatter diagram all points will appear automatically in the same color (Note: To obtain a raster object choose a filled rectangle as point symbol by double clicking on the XY points. Vary the size of the rectangles so that a completely filled surface results, approximately 20 pt).

For the individual predominant species to appear each in a different color, click with the right mouse button in the diagram and choose the window “data source”. Under “row” you can define a data series for each species (per default, there is only one database with the name “pe” comprising all species). Further data series can be defined by using “Add”, e.g. the series  $\text{Fe}^{2+}$ , with name ( $\text{Fe}^{2+}$ ), X value (as found in the table, e.g. in column A from row 146 to 268) and the respective Y values (B 146 – B 268). The X and Y values can be defined most simply by clicking with the mouse on the red arrow beside the cells for X values and Y values and mark the respective cells in the table (A146-A268 for X, B146-B268 for Y). As soon as a data serie has been defined for each species, different colors will be assigned automatically. A raster-pE-pH-diagram is obtained reflecting the predominance of individual species by differently colored zones.

Create a pE-pH-diagram of the predominant iron species in a solution, which contains 10 mmol/L Fe and 10 mmol/L Cl. Vary pH and pE values from 0 to 14 and from -10 to +20, respectively, in steps of 1 as well as of 0.5.

### ***3.1.3.2 The Fe pE-pH diagram considering carbon and sulfur***

How does the pE-pH diagram created in chapter 3.1.3.1 change when 10 mmol/L  $\text{S}(6)$  or 10 mmol/L  $\text{C}(4)$  in solution are taken into account?

### ***3.1.3.3 The pH dependency of uranium species***

An acid mine water mixes downstream of a mine with groundwater of the following chemical composition (Table 34).

How do the uranium species change? Which species predominate at which pH value? What are the effects of the change in uranium species concerning processes of transport and sorption?

**Table 34** Water analysis of an acid mine drainage AMD (pH = 2.3) and of a groundwater GW (pH = 6.6) (concentrations in mg/L)

	GW	AMD		GW	AMD		GW	AMD
pE	6.08	10.56	Cu	0.005	3	Ni	0.005	5
Temperature	10	10	F	0.5	1	NO <sub>3</sub> <sup>-</sup>	0.5	100
Al	3.0	200	Fe	0.6	600	Pb	0.05	0.2
As	0.004	2	K	1.5	4	pH	6.6	2.3
C(4)	130		Li	0.02	0.1	Si	3.64	50
Ca	36.6	400	Mg	3.5	50	SO <sub>4</sub> <sup>2-</sup>	14.3	5000
Cd	0.0003	1	Mn	0.07	20	U	0.005	40
Cl	2.1	450	Na	5.8	500			

*Note: The PHREEQC keyword for mixing two waters is MIX. Here you have to enter the number of the solution and the percentage, to which the solution contributes to the mixture. Assuming a mixture of 25 % from solution 1 and 75 % from solution 2 may be expressed in the one or the other form:*

<i>MIX</i>	<i>MIX</i>
<i>1 0.25</i>	<i>1 1</i>
<i>2 0.75</i>	<i>2 3</i>

When mixing the acid mine drainage, assume that it will be diluted 1:1 with groundwater. Dilute this water again 1:1 with groundwater and so on until you obtain more or less pure groundwater. Save the first 1:1 diluted solution using the keyword SAVE\_SOLUTION 3, terminate the job with END, and start the next job with USE\_SOLUTION 3, etc.

### 3.1.4 Origin of groundwater

#### Inverse modeling

The determination of the origin of groundwater is an important aspect of hydrogeological investigations. For establishing drinking water protection zones e.g. it is necessary to know the groundwater's origin to determine possible geogenic or anthropogenic contamination potential and its impact on the extracted groundwater.

The basic idea is to reconstruct geochemical evolution of the groundwater from its chemical composition. For example, knowing the chemical composition of a well on the one hand and an analysis of the rainwater on the other, it will be possible to reconstruct which geological formation the rainwater must have passed after its infiltration to change its chemical composition as the result of reactions with mineral and gas phases (dissolution, precipitation, degassing) in a way that accounts for the composition of the water from the well.

*The keyword in PHREEQC is "Inverse Modeling". The primary solution(s) (rainwater) and the final product (well water) have to be defined as SOLUTION*

as well as the involved mineral- and gas phases as PHASES. The structure of such a job follows:

```

TITLE Inverse Modeling
SOLUTION 1      # original water (rainwater)
SOLUTION 2      # water after the reaction with minerals and gases
                  # (well water)

INVERSE MODELING
  - solutions 1 2  # solution 1 transforms into solution 2
  - uncertainty 0.1 # 10 % uncertainty equally defined for all elements in
                    # the analysis and both waters 1 and 2
  - balance Ca 0.2 0.3 # for special elements higher uncertainties can
                        # be defined, e.g. for elements whose
                        # determination underlies a greater error,
                        # e.g. 20 % error for the amount of Ca in
                        # solution 1 and 30 % error for the amount of
                        # Ca in solution 2
  - phases
    K-mica  dissolve # mica can only be dissolved
    CO2(g)  # both dissolution and degassing possible
    SiO2(a) # both dissolution and precipitation possible
    Kaolinite precip # allow only for precipitation

END # end of the job

```

*Note: For each element in solution 1 or solution 2, a mineral or gas phase has to be defined under PHASES that contains this element. Otherwise PHREEQC reports the following problem: “element is included in solution 1, but is not included as a mass-balance constraint”. The modeling can still be continued, however the respective element is not considered for the mass balance.*

*The number of the mineral phases as well as the size of the uncertainty should be varied to simulate different possible situations. Maybe the program does not find a valid model after the first calculation. Then the mineral phases have to be changed or completed or the uncertainty has to be increased, whereas of course uncertainties of > 10 % do not permit any reliable predictions anymore. Also including as many mineral and gas phases as possible, does not help. The main goal is to exclude as many reaction pathways as possible and find others with a minimum of necessary gas and mineral phases.*

*Depending on the number of mineral phases and the uncertainty chosen the program displays one or more models in the output. Each model describes how much of each mineral was dissolved or precipitated to transform solution 1 (rainwater) into solution 2 (well water) (keyword: phase mole transfers). If you enter several initial solutions (e.g. 5 analyses of rainwater from 5 individual altitudes), the program will also calculate the share of the respective rainwater solutions contributing to the final solution (well water).*

### 3.1.4.1 Pumping of fossil groundwater in arid regions

50 L/s groundwater of the following composition (Table 35) are extracted from a well in an arid zone.

**Table 35** Water analysis of a groundwater (pH = 6.70, temperature = 34.5 °C, concentrations in mg/L)

K	2.42	Na	12.96	Ca	247.77	Mg	46.46
Alkalinity	253.77	Cl	6.56	NO <sub>3</sub> <sup>-</sup>	2.44	SO <sub>4</sub> <sup>2-</sup>	637.75
SiO <sub>2</sub>	4.58	<sup>13</sup> C	-6 ± 0.8	<sup>2</sup> H	-68 ± 0.6	<sup>18</sup> O	-9.6 ± 0.3

It is known that only a small amount of the extracted groundwater originates from recent groundwater resources (Table 36). The rest is extracted from a reservoir of fossil water that has formed 20,000 years ago when temperatures were considerably lower in that area than they are today.

The fossil water is characterised by high total mineralization as a result of long residence times in the subsurface as well as by lower <sup>2</sup>H and <sup>18</sup>O isotope values as a result of the lower temperatures during formation (Table 37). The different amounts of <sup>13</sup>C can be explained by the establishment of equilibrium of the fossil groundwater with marine limestones with higher amounts of <sup>13</sup>C than recent groundwater, which reflects the lower concentrations of <sup>13</sup>C in the atmosphere.

**Table 36** Water analysis of a recent groundwater (pH = 6.70, temperature = 28.0 °C, concentrations in mg/L)

K	2.87	Na	14.60	Ca	72.60	Mg	20.50
Alkalinity	247.97	Cl	4.00	NO <sub>3</sub> <sup>-</sup>	4.52	SO <sub>4</sub> <sup>2-</sup>	69.96
SiO <sub>2</sub>	32.16	<sup>13</sup> C	-22 ± 1.4	<sup>2</sup> H	-52 ± 0.5	<sup>18</sup> O	-7.5 ± 0.3

**Table 37** Water analysis of a fossil groundwater (pH = 6.90, temperature = 40 °C, concentrations in mg/L)

K	3.33	Na	18.41	Ca	351.80	Mg	65.96
Alkalinity	298.29	Cl	9.00	NO <sub>3</sub> <sup>-</sup>	1.35	SO <sub>4</sub> <sup>2-</sup>	906.15
SiO <sub>2</sub>	20.74	<sup>13</sup> C	0 ± 0.4	<sup>2</sup> H	-76 ± 0.7	<sup>18</sup> O	-10.5 ± 0.4

Apply inverse modeling to determine how much of the extracted groundwater originates from the reservoir of fossil water. Also take into account that the extracted groundwater has been in contact with sandstones, dolomitic limestones, gypsum and halite and that under the given conditions neither dolomite nor gypsum nor halite will precipitate. Assume precipitation for calcite and degassing of CO<sub>2</sub>.

If the amount of fossil water in the extracted groundwater is known an estimation can be given on how long it will take to completely exploit the approximately 5 m high, 1 km wide and 10 km long reservoir assuming a constant rate of production of 5 L/s.

*Note: Remember the explanation in the introduction of chapter 3.1.4 that the portions of several initial solutions on the final solution can be modeled with the help of the inverse modeling!*

*To include the isotopes in the modeling, they have to be defined under each respective SOLUTION using the sub keyword “isotope”.*

#### **SOLUTION**

*-isotope [name of the isotope in the following form: mass number element] [value in %, pmc or as ratio] [uncertainty in % (possible, but not necessary)], e.g.*

*-isotope 13C -6 0.8*

*Instead of the sub keywords -isotope the abbreviation -i can be used.*

*Isotope data can only be used for inverse modeling. There, the respective isotopes have to be listed again under the keyword Inverse\_Modeling and under the sub keyword -isotopes, e.g.*

*INVERSE\_MODELING*

*-isotopes*

*13C*

*2H*

*18O*

*Additionally for each mineral or gas phase containing these isotopes their share has to be defined (mean value, in the example 2 ‰ and deviation, in the example  $\pm 2$  ‰) and whether the respective phase shall be dissolved or precipitated, e.g.*

*-phases*

*calcite                      pre        13C        2.0        2*

*Consider an average concentration of  $^{13}\text{C}$  between 1-5 ‰ for dolomite, 0-4 ‰ for calcite and -20 to -30 ‰ for  $\text{CO}_2$ . The isotopes  $^2\text{H}$  and  $^{18}\text{O}$  can only be found in the water molecule. Therefore they do not have to be defined for a mineral phase. If you want to keep the option of dissolution or precipitation open, define the mineral phases twice, once using dis (dissolve), and a second time using pre (precipitate).*

#### **3.1.4.2 Salt water/fresh water interface**

As a result of the groundwater extraction in coastal areas, seawater intrusions occur, leading to a mixture of salt water and fresh water. Such a mixed groundwater of the following chemical composition is extracted from the irrigation water well B1 in the model area west of the town (Fig. 57): pH = 6.58, temperature = 13.4 °C, Ca = 3.724e-03 mol/L, Mg = 1.362e-02 mol/L, Na = 1.080e-01 mol/L, K = 2.500e-03 mol/L, C = 7.067e-03 mol/L, S = 6.780e-03 mol/L, Cl = 1.261e-01 mol/L, P = 7.542e-06 mol/L, Mn = 8.384e-10 mol/L, Si = 1.641e-05 mol/L, Fe = 8.248e-09 mol/L.

The results of the analysis of the seawater are as follows: pH = 8.22, temperature = 5.0 °C, Ca = 412.3 mg/L, Mg = 1291.8 mg/L, Na = 10768.0 mg/L,

K = 399.1 mg/L,  $\text{HCO}_3^-$  = 141.682 mg/L,  $\text{SO}_4^{2-}$  = 2712.0 mg/L, Cl = 19353.0 mg/L, Si = 4.28 mg/L, Mn = 0.0002 mg/L, Fe = 0.002 mg/L. Furthermore, consider a higher density for seawater ( $1.023 \text{ g/cm}^3$ )!

The following analysis is given for the Quaternary aquifer: pH = 6.9, temperature = 18 °C, Ca = 65.9 mg/L, Mg = 40.1 mg/L, Na = 3.5 mg/L, K = 7.5 mg/L,  $\text{HCO}_3^-$  = 405.09 mg/L,  $\text{SO}_4^{2-}$  = 23.4 mg/L, Cl = 15.8 mg/L,  $\text{PO}_4^{3-}$  = 0.921 mg/L.

Determine the origin of the mixed groundwater (i.e. the share of seawater and fresh groundwater) taking into account the geological features around the irrigation water well. Keep in mind that there is no distinct aquiclude between the Quaternary and the Cretaceous aquifer.

*Note: In general, check each analysis regarding the analytical error and enforce, if necessary, a charge balance when the deviations are too high before starting the modeling.*

### 3.1.5 Anthropogenic use of groundwater

#### 3.1.5.1 Sampling: Ca titration with EDTA

To determine the amount of calcium in a water sample, e.g. titration with EDTA (ethylenediaminetetraacetate,  $\text{C}_2\text{H}_4\text{N}_2(\text{CH}_2\text{COOH})_4$ ) can be used. First of all, NaOH is added to the sample to obtain a pH value of at least 12. Then, a color indicator is added and the titration with EDTA is performed until the color changes. In doing so, all Ca is converted to a Ca-EDTA complex and detected in this form.

Model the determination of the concentration of Ca for the following analysis with PHREEQC: pH = 6.7, temperature = 10.5 °C,  $\text{Ca}^{2+}$  = 185 mg/L,  $\text{Mg}^{2+}$  = 21 mg/L,  $\text{Na}^+$  = 8 mg/L,  $\text{K}^+$  = 5 mg/L, C(4) = 4.5 mmol/L,  $\text{SO}_4^{2-}$  = 200 mg/L, Cl = 90 mg/L,  $\text{NO}_3^-$  = 100 mg/L.

The amount of EDTA that has to be added until the color changes is unknown. Therefore, EDTA is added step by step and the titration is continued beyond the point of color change. The point of color change will be determined afterwards using the obtained graph.

*[EDTA cannot be found in the previously used database WATEQ4F.dat. It is only defined in the database MINTEQA.dat. Therefore, use this one. The keyword for the addition of EDTA is the same as for the exercise in chapter 3.1.1.9.]*

#### 3.1.5.2 Carbonic acid aggressiveness

In drinking water standards it is often required that “water should not be aggressive”. In most cases this “aggressiveness” refers to the carbonic acid. The reason for the requirement of a low aggressiveness is not of toxicological but of technical nature since carbonic acid waters easily corrode pipeline materials (concrete, metals, plastics). Regulations therefore recommend that the measured

pH value shall only differ  $\pm 0.2$  pH units from the pH<sub>c</sub> (the pH value at calcite saturation) ( $\Delta\text{pH} = \text{pH} - \text{pH}_c$ ). The aim is to have a pH value that is slightly above the pH<sub>c</sub> value (0.05 pH units) because then a protective layer can develop on the pipe walls. On the contrary, significant supersaturation ( $\Delta\text{pH} > 0.2$ ) leads to noticeable calcite deposits within the pipes and potential blockages which is as undesirable as undersaturation ( $\Delta\text{pH} < -0.2$ ), which leads to corrosion.

Additionally, potable water should not exceed pH values of 9.5 or fall below pH values of 6.5.

Consider these technical requirements when checking if the potable water extracted from the drinking water well B3 in the model area (chapter 3.1.1.1, Fig. 57) can be used without further treatment.

### 3.1.5.3 Water treatment by aeration – well water

Check whether an open aeration (equilibrium with atmospheric CO<sub>2</sub>, open system) would help to meet the requirements concerning the pH as well as the  $\Delta\text{pH}$  for the drinking water which is extracted from well B3 in the model area (Fig. 57).

[Note: For simulating the open aeration and the calculation of the new pH<sub>c</sub> in one job, use the commands `SAVE_SOLUTION`, `END` and `USE_SOLUTION 1` like in the exercise in chapter 3.1.3.3.]

### 3.1.5.4 Water treatment by aeration – sulfur spring

For the little village as well as for some individual farms in the eastern part of the model area (Fig. 57), a possibility for drinking water supply is sought. The spring discharging east of the village shall be investigated for suitability. The hydrogeochemical data can be found in Table 38.

**Table 38** Water analysis of a spring water (concentrations in mg/L)

pH	6.5		
Redox potential	-120 mV	Al	0.26
Temperature	10.7 °C	SiO <sub>2</sub>	24.68
O <sub>2</sub>	0.49	Cl	12.76
Ca	64.13	HCO <sub>3</sub>	259.93
Mg	12.16	SO <sub>4</sub>	16.67
Na	20.55	H <sub>2</sub> S	2.33
K	2.69	NO <sub>3</sub>	14.67
Fe	0.248	NH <sub>4</sub>	0.35
Mn	0.06	NO <sub>2</sub>	0.001

Illustrate the species distribution for the elements aluminium, iron(II), and iron(III). Then, model a water treatment in terms of an open aeration with atmospheric oxygen (oxidation!). What happens to the Al and Fe species? Which mineral phases will presumably precipitate during the aeration?

Vary the partial pressure of oxygen. What is remarkable?

Is the pH value after the aeration still within the limits required for potable water?

To set up the dimensions of a water treatment plant correctly, it is important to know the amount of sludge that will form every day as a result of the precipitation of mineral phases. Enforce the precipitation of the mineral phases that are most likely to precipitate during aeration in your model and calculate the accumulating amount of sludge per day assuming a production rate of 30 L/s in the future water treatment plant. Do not forget that sludge does not only consist of the precipitated mineral phases but mainly of water (60-90 %).

Evaluate your model with regard to the elements N and S. What will the results rather look like in reality and why?

### ***3.1.5.5 Mixing of waters***

Not far from the drinking water well B3 in the model area (Fig. 57) there is an older, abandoned well B4 that has been shut down for several years as it did not meet the quality requirements for potable water anymore. Recent investigations showed the following result: pH = 6.99, temperature = 26.9°C,  $\text{Ca}^{2+}$  = 260 mg/L,  $\text{Mg}^{2+}$  = 18 mg/L,  $\text{Na}^+$  = 5 mg/L,  $\text{K}^+$  = 2 mg/L,  $\text{HCO}_3^-$  = 4 mmol/L,  $\text{SO}_4^{2-}$  = 260 mg/L,  $\text{Cl}^-$  = 130 mg/L,  $\text{NO}_3^-$  = 70 mg/L.

It is planned to reactivate the well B4 to support peak times of water consumption and to mix the extracted water with that of the current drinking water well B3. Check with the help of PHREEQC modeling if and in which shares this can be done with regard to general requirements of drinking water standards and to the technical requirements in terms of the calcite-carbondioxide equilibrium (chapter 3.1.5.2). [*keyword for mixing of two waters see exercise in chapter 3.1.3.3.*]

### ***3.1.6 Rehabilitation of groundwater***

#### ***3.1.6.1 Reduction of nitrate with methanol***

Groundwater from the exercise in chapter 3.1.5.1 in an area with intensive agriculture shows extremely high concentrations of nitrate due to years of excessive fertilization. Methanol as a reducing agent shall be pumped into the aquifer via infiltration wells to reduce the pentavalent nitrogen (nitrate) to the zero valent gas nitrogen. The latter can degas leading to a decrease of nitrate concentrations in the aquifer. How many liters of a 100 % methanol solution (density of methanol = 0.7 g/cm<sup>3</sup>) per m<sup>3</sup> aquifer have to be pumped into the aquifer to guarantee an effective reduction of nitrate concentrations? What effect could an “overdose” of methanol have?

### 3.1.6.2 *Fe(0) barriers*

Reactive barriers of elemental iron are used to reduce groundwater constituents in-situ and thus, to convert e.g. mobile uranium(VI) into uranium(IV) that precipitates as uraninite ( $\text{UO}_2$ ). At the same time, the elemental iron in the reactive barriers oxidizes and iron hydroxide and subsequently crusts of iron oxide form. Precipitated iron hydroxides and uraninite reduce the reactivity of the barrier after a certain time.

The uranium containing mine water of the exercise in chapter 3.1.3.3 shall be cleaned by means of such a reactive barrier. How much iron per  $\text{m}^2$  has to be used considering a percolation of the reactive barrier of  $500 \text{ L/d}\cdot\text{m}^2$  to reduce the amount of uranium from  $40 \text{ mg/L}$  to at least one third taking into account that the barrier shall be in operation for approximately 15 years? How much uraninite will precipitate?

### 3.1.6.3 *Increase in pH through a calcite barrier*

To increase the pH of the acid mine drainage from the exercise in chapter 3.1.3.3 a reactive wall of 1 m thick calcite (density of calcite =  $2.71 \text{ g/cm}^3$ ) shall be installed within the aquifer. Thickness and permeability of the wall are chosen in a way that a 50 % saturation of lime in the aquifer can be reached with a daily percolation of  $500 \text{ L/m}^2$ .

Does the calcite wall lead to the desired increase of the pH value? Why are there still objections against the reactive calcite wall taking into account the long-term efficiency and premature alteration? Which carbonates could be chosen alternatively to calcium carbonate to avoid a premature alteration?

## 3.2 Reaction kinetics

### 3.2.1 *Pyrite weathering*

Diffusion calculations for a covered heap containing pyrite show that  $0.1 \text{ m}^3$  of oxygen enter the heap every day by diffusion. It is assumed that this oxygen is completely consumed by pyrite oxidation within one day. Therefore, reaction kinetics is exclusively determined by the diffusion rate of the oxygen into the heap. An average of 0.1 mm of rainwater infiltrates through the heap cover daily. The rainwater has a pH of 5.3, a temperature of  $12^\circ\text{C}$  and is in equilibrium with the  $\text{CO}_2$  and  $\text{O}_2$  partial pressure of the atmosphere. The heap covers an area of  $100 \text{ m} \times 100 \text{ m}$ , has a height of 10 m, and a pyrite concentration of 2 Vol%. The following questions are to be solved:

1. What is the chemical composition of the seepage water discharging at the foot of the heap along the base sealing?
2. What happens when water at the foot of the heap gets in contact with atmospheric oxygen?

3. How many years will it take until all pyrite in the heap is consumed?
4. How much carbonate has to be added during the heap construction to neutralise the pH value? Is it possible to reduce the amount of sulfate at the same time?
5. How does the necessary amount of carbonate change when assuming that a CO<sub>2</sub> partial pressure of 10 Vol% will develop within the heap as a result of the decomposition of organic matter?

Instead of assuming an oxygen diffusion rate as in this example, it is also possible to define a pyrite oxidation rate  $R$  that is a function of e.g. O<sub>2</sub>, pH, temperature, the amount of microorganisms and the nutrient supply. Examples using direct reaction rates in PHREEQC follow in the next exercises.

### 3.2.2 Quartz-feldspar-dissolution

Model the dissolution of quartz and K-feldspar (adularia) over time. Are the parameters temperature and CO<sub>2</sub> partial pressure of any importance? Within the keyword `RATES` use the `BASIC` program from the database `PHREEQC.dat`. The calculation is done with distilled water (pH = 7, pE = 12) as a batch reaction over a time span of 10 years in 100 time steps at a temperatures of 5 °C and of 25 °C and at CO<sub>2</sub> partial pressures of 0.035 Vol% (atmosphere) and of 0.7 Vol% (soil). Calculate also the kinetics of the dissolution with 0.035 Vol% CO<sub>2</sub> and 25 °C for a period of 10 minutes.

*[Note: The database `WATEQ4F.dat` uses the name `adularia` for K-feldspar. Use `EQUILIBRIUM_PHASES` to fix the oxygen concentration to 21 Vol%. Enter quartz with "0 0" under the same keyword. While the first zero limits the solubility to 100% saturation, the second zero indicates the possible amount of quartz added in moles. Zero means no further quartz addition (dissolution), i.e. that the 100% saturation can only be achieved through precipitation at supersaturation, but not through dissolution at undersaturation. This step is necessary, since the dissolution will be defined using `KINETICS` and `RATES`. It is quite useful, too, to limit the solubility of aluminium by the precipitation of e.g. kaolinite. In the simplest case this can be done by `EQUILIBRIUM_PHASES` as well since this precipitation occurs spontaneously and fast. Thus, a kinetic modeling is not necessary.]*

*Using the minerals quartz and kaolinite in `EQUILIBRIUM_PHASES` causes a problem in PHREEQC regarding the elements Si and Al because they do not occur within the keyword `SOLUTION`. Therefore you have to specify them in very small quantities in the solution (e.g. 1 µg/L). Furthermore, the sub keyword `step_divide 100` within the keyword `KINETICS` is necessary. The output can be obtained most effectively using `SELECTED_OUTPUT`.]*

### 3.2.3 Degradation of organic matter within the aquifer on reduction of redox-sensitive elements (Fe, As, U, Cu, Mn, S)

The degradation of organic matter results in the consumption of oxygen. Under certain circumstances, this may lead to the reduction of oxygen-containing anions like nitrate (see also the exercise in chapter 3.1.6.1) and sulfate, as well as to the reduction of redox-sensitive elements like iron, manganese, or uranium. The decomposition of organic matter depends on the presence of microorganisms and is thus always connected to kinetics.

The reactions in an aquifer shall be modeled in the presence of calcite and large concentrations of pyrite and organic matter for the acid mine drainage from the exercise in chapter 3.1.3.3. As no inorganic carbon is given in the analysis and calcite is to be used as kinetically reacting mineral in the model, the analysis has to be completed by e.g. 1 mg/L carbon, formally.

PHREEQC always refers to one liter or one kg of water. The model describes a batch reaction with 1 liter water. 10 mmol calcite as well as 1 mol pyrite and 1 mol organic matter shall be present in the respective sediment/rock. To describe the kinetics of calcite and pyrite, the BASIC program given at the end of the database PHREEQC.dat is used. For the degradation of organic matter the PHREEQC.dat notation is used, too. However, the lines 50 and 60 have to be changed as follows to accelerate the decomposition of the organic matter. Nitrate is not taken into account in this example.

```
50  rate = 1.57e-7*mO2/(2.94e-4 + mO2)
```

```
60  rate = rate + 1.e-10*mSO4/(1.e-4 + mSO4)
```

Since there is no general definition for organic matter in any of the databases which are installed with the PHREEQC program, a name has to be assigned in the kinetics data block (e.g. Organic\_C) and the organic matter has to be specified using the keyword “-formula”. Use the general formula  $\text{CH}_2\text{O}$ .

```
-formula CH2O
```

KINETICS needs three parts for organic matter, pyrite, and calcite, respectively. It is not relevant, in which block the time steps are defined. Using “-step\_divide 1000000”, the step width is cut down at the beginning of the kinetic calculations according to the quotient total time/step\_divide.

Since all calcite is dissolved after 100 days at the latest, the following line for the calcite kinetics is inserted at the beginning of the BASIC program to save calculation time:

```
5  if time > 8640000 then goto 200
```

The simulation time is 10,000 days in 100 intervals (steps). To obtain a higher temporal resolution at the beginning of the simulation, calculate a second model with only 600 days in 100 intervals.

### 3.2.4 Degradation of tritium in the unsaturated zone

If the unsaturated zone is composed of relatively fine sediment (silt and fine sands) a quasi-uniform seepage flow can be assumed for the unsaturated zone in humid climate zones over long time spans. Therefore, the transport of infiltrated water can be simulated in PHREEQC as a monotonous movement in accordance with the "piston flow" model. A constant flow of infiltration water of 0.5 m per year is assumed for the following simulation. Furthermore, it is considered simplistically that the infiltrating precipitation has a tritium activity of 2000 TU (tritium units) over a period of 10 years. Then, it is assumed that the tritium activity decreases to zero again.

The following example shows how this can be modeled in PHREEQC. First of all, a master and a solution species tritium T or T<sup>+</sup> have to be defined. Since the input of data for log<sub>k</sub> und -gamma within the keyword SOLUTION\_SPECIES is required, but unknown, any value can be entered here as a free parameter ("dummy", e.g. 0.0). This value is not used for kinetic calculations and thus, does not cause any problems. However, all results based on equilibrium calculations (e.g. the calculation of the saturation index) are nonsense for this "species". The tritium values have to be entered in tritium units (T.U.). However, in order not to have to define or convert them in an extra step, they are entered fictitiously with the unit umol/kgw instead of T.U. in PHREEQC. As no interactions of tritium with any other species are defined, the unit is eventually irrelevant. After modeling, remember that the result is displayed in mol/kgw as always in PHREEQC and has to be recalculated to the fictitious tritium unit umol/kgw. Entering mol/kgw in the input file, the solution algorithm quits due to problems with too high total ionic strengths.

The unsaturated zone is 20 m and is subdivided into 40 cells, 0.5 m each, so that a "time step" is exactly 1 year = 86400 \* 365 seconds = 3.1536e+7 seconds. The half-life of tritium (12.3 years) has to be entered in seconds in PHREEQC. First, the created 1D soil column is saturated with water containing no tritium (solution 1-40). Then, water with 2000 T.U. is added over a period of 10 "shifts" (= 10 years) (*Note: solution 0 is always the solution which is added on top of the column*). After this high tritium impulse, the solution is changed again to water containing no tritium, which percolates through the column for another 30 years. The two changes from water with 0 T.U. to 2000 T.U. and back again from 2000 T.U. to 0 T.U. are two different jobs that have to be separated by END.

The degradation of tritium is described as a 1<sup>st</sup> order kinetic reaction as follows (see also Table 13):

$$\frac{d(A)}{dt} = -K_k \cdot (A)$$

$$t_{1/2} = \frac{1}{K_k} \cdot \ln 2$$

PHREEQC Job: Tritium in the unsaturated zone – impulse-like input function

Fig. 59 shows a vertical cross section of tritium concentrations resulting from an impulse-like input of tritium into the unsaturated zone after 10, 20, 30, and 40 years. The tritium peak moves downward and widens continuously.

The actual task now is to change the PHREEQC job in such a way that the tritium input function is not impulse-like but more realistic. Fig. 60 illustrates the increase of tritium concentrations in precipitation water from 1962 to 1963 and the subsequent decrease from 1963 to 1997, as determined at the climate station Hof-Hohensaas, Germany.

Fig. 59 Vertical cross section of tritium in the unsaturated zone (0-20 m depth) for the time intervals 10, 20, 30, 40 years assuming an impulse-like input during the first ten years

**Fig. 60** Tritium concentration in rainwater, measured at the station Hof-Hohensaas, Germany (latitude 50.32 °N, longitude 11.88 °E, height 567 m NN) from 1962 to 1997

The definition of a more realistic tritium input function based on the available data of the tritium concentrations in the rainwater is done in time intervals of 5 years each (Table 39).

**Table 39** Tritium concentrations in the atmosphere from 1962 to 1997

Intervall of 5 years	Tritium in the atmosphere (T.U.)
1 (06/1962 - 06/1967)	1022
2 (07/1967 - 07/1972)	181
3 (08/1972 - 08/1977)	137
4 (09/1977 - 09/1982)	64
5 (10/1982 - 10/1987)	24
6 (11/1987 - 11/1992)	17
7 (12/1992 - 12/1997)	13

Remodel the degradation of tritium in the unsaturated zone with this new input function. Compare your results with the results obtained from the assumption of an impulse-like tritium input in Fig. 59.

**3.3 Reactive transport**

**3.3.1 Lysimeter**

A lysimeter filled with sediments was equilibrated with the following water (concentrations in mmol/L):

pH = 8.0, pE = 12, temperature = 10.0 °C, Ca = 1, C = 2.2, Mg = 0.5, K = 0.2,  $\text{SO}_4^{2-} = 0.5$

At a time T1, an acid mine drainage of the following composition is added (concentration in mmol/L):

pH = 3.2, pE = 16, temperature = 10.0° C, Ca = 1, C = 2.0, Mg = 0.5, K = 0.2,  $\text{SO}_4^{2-} = 4.0$ , Fe = 1, Cd = 0.7, Cl = 0.2

Calculate the distribution of the concentrations within the lysimeter column taking into account the cation exchange (discretisation and time steps as in the example in chapter 2.2.2.5). Selectivity coefficients are taken from the exemplary data of WATEQ4F.dat database and an exchange capacity of 0.0011 mol per kg water is assumed. Neither diffusion nor dispersion is considered. Present your results graphically.

### 3.3.2 Karst spring discharge

A karst water has the following chemical composition:

pH = 7.6, pE = 14.4, temperature = 8.5 °C, Ca = 147,  $\text{HCO}_3^- = 405$ , Mg = 22, Na = 5, K = 3,  $\text{SO}_4^{2-} = 25$ , Cl = 12,  $\text{NO}_3^- = 34$  (concentrations in mg/L)

Fig. 61 Calcite ridge at a karst spring discharge near Weißenburg, Germany.

It is in equilibrium with a  $\text{CO}_2$  partial pressure of 0.74 Vol% and is slightly supersaturated with regard to calcite ( $\text{SI} = 0.45$ ). This karst water discharges at a spring with a mean discharge of 0.5 L/s and flows in a small channel downhill with a mean velocity of 0.25 m/s. Due to the turbulent flow,  $\text{CO}_2$  will degas spontaneously until equilibrium is reached with the  $\text{CO}_2$  partial pressure of the

atmosphere. Because of the resulting carbonate precipitation, the creek forms a small carbonate ridge over the years, on top of which it flows in a small channel (Fig. 61).

Model the carbonate precipitation in this carbonate channel by means of a 1D transport with 40 cells of 10 m length each. Dispersivity is assumed with 1m. Use the keywords KINETICS and RATES and the BASIC program for calcite from the database PHREEQC.dat describing the kinetics for both the calcite dissolution and the calcite precipitation. How much calcite precipitates each year within the channel's first 400 meter after the discharge? How much CO<sub>2</sub> degasses at the same time?

*[Note: For all n cells a SOLUTION has to be defined at the beginning of the modeling (SOLUTION 1-n). The same applies for the keywords KINETICS and EQUILIBRIUM PHASES. If you use 1 instead of 1-n, the kinetic or the equilibrium reactions would only be modeled for the first cell.]*

### 3.3.3 Karstification (corrosion along a karst fracture)

Talking about karstification often the question arises why karst phenomena do not only occur at the surface but in greater depths as well. The reason is that the carbonate dissolution is a comparatively fast process, but still takes some time, while water may cover quite a long distance along a fracture.

This shall be modeled with the following example. A fracture with an extension of 300 meters is given. Assume that, at the beginning of the simulation, this fracture is filled with groundwater that is in carbonate equilibrium. To simplify matters the following data shall be used:

pH	7.32
Temp	8.5
C	4.905 mmol/L
Ca	2.174 mmol/L

Infiltrating rainwater now dissolves CO<sub>2</sub> according to the increased partial pressure of 1 Vol% in the unsaturated zone. Thus, the seepage water has the following characteristics:

pH	4.76
Temp	8.5
C	0.5774 mmol/L

This water enters the model fracture with a velocity of 10 m per 6 minutes. Calculate the carbonate dissolution in the 300 meter long fracture that will be modeled as a one dimensional pipe with 30 elements of 10 m length each. Furthermore, consider a dispersivity of 0.5 m and assume that the whole water column will be exchanged once. Moreover, the fracture is not completely filled with water, but contains air, too. This air has a CO<sub>2</sub> partial pressure of 1 Vol%. The kinetics of the carbonate dissolution shall be assumed according to chapter 2.2.2.3.1. Further, use the keyword USER\_GRAPH to visualize the result graphically within PHREEQC. The concentrations of Ca and C as well as the

calcite saturation index shall be displayed along the 300 m long fracture after a single exchange with the infiltrating rainwater.

### 3.3.4 The pH increase of an acid mine water

Acid mine drainages (AMD) cause great problems in the mining industry as they typically contain high concentrations of iron, sulfate, and protons due to the pyrite oxidation. Consequently, other elements (e.g. metals and arsenic) may be increased as well. A simple method of water treatment is to conduct these acid waters through a carbonate channel. This process causes an increase of the pH value due to carbonate dissolution. Furthermore, it can result in supersaturation of other minerals that can precipitate spontaneously. The high sulfate concentrations combined with increasing calcium values from the calcite dissolution often exceed the gypsum solubility-product. Iron minerals are also supersaturated as a result of these reactions, and consequently e.g. amorphous iron hydroxide precipitates spontaneously. Even though the dissolution of calcite is relatively fast this exercise shows that the reaction kinetics still has to be taken into account to plan the dimensions of such a carbonate channel correctly. An acid mine drainage (“AMD”) and a natural surface water are given (Table 40).

**Table 40** Water analysis of an acid mine drainage (“AMD”) and of a natural surface water (“SW”)

Parameter	AMD	SW	Parameter	AMD	SW
pe	6.08	6.0	K	3.93e-05 mol/L	1.5 mg/L
Temp.[°C]	10	10	Li	2.95e-06 mol/L	
pH	1.61	8.0	Mg	1.47e-04 mol/L	3.5 mg/L
Al	1.13e-04 mol/L		Mn	1.30e-06 mol/L	
As	5.47e-07 mol/L		NO <sub>3</sub> <sup>-</sup>	2.47e-04 mol/L	0.5 mg/L
TIC*)	3.18e-03 mol/L		Na	2.58e-04 mol/L	5.8 mg/L
HCO <sub>3</sub> <sup>-</sup>		130 mg/L **)	Ni	8.72e-07 mol/L	
Ca	9.19e-04 mol/L	36.6 mg/L ***)	Pb	2.47e-07 mol/L	
Cd	2.27e-07 mol/L		SO <sub>4</sub> <sup>2-</sup>	5.41e-02 mol/L	14.3 mg/L
Cl	6.07e-05 mol/L	2.1 mg/L	Si	6.20e-05 mol/L	3.64 mg/L
Cu	8.06e-07 mol/L		U	2.15e-07 mol/L	
F	2.69e-05 mol/L		Zn	1.09e-05 mol/L	
Fe	2.73e-02 mol/L	0.06 mg/L			

\*) total inorganic carbon

\*\*) adjust inorganic C to the partial pressure of the atmosphere (CO<sub>2</sub>(g) -3.5)

\*\*\*) set Ca to “charge” in the PHREEQC input file

At the beginning of the modeling the 500 m long carbonate channel is filled with the surface water (“SW”). Then, the acid mine water is added. Calculate how the composition of the mine water changes, how much calcite is dissolved and how much gypsum and iron hydroxide precipitate. Additional problems like coating of the carbonate by gypsum and iron hydroxide crusts as well as the kinetics of the formation of gypsum and iron hydroxide are ignored in this model.

Apply 1 m/s as flow velocity so that the total contact time in the channel is 500 seconds. The modeling should be done as 1D transport model with 10 cells (dispersivity: 0.1 m) and last over 750 seconds. Also take into account the contact with the atmosphere. Therefore, run the model once with a CO<sub>2</sub> partial pressure of 0.03 Vol% and a second time with 1 Vol%, both times assuming an oxygen partial pressure of 21 Vol% O<sub>2</sub>. The latter case corresponds rather to a closed carbonate channel.

Illustrate the results of the model by presenting the water characteristics over the whole length of the channel at the end of the modeling (pH value, SI calcite, Ca, Fe, C, SO<sub>4</sub><sup>2-</sup>, CaSO<sub>4</sub><sup>0</sup>). Additionally indicate the amounts of calcite dissolved and of gypsum and iron hydroxide precipitated.

### 3.3.5 In-situ leaching

Aquifers with double porosity (e.g. sandstones with fractures and pore volume) require special considerations with regard to transport modeling even if no reactive mass transport in its proper sense is taken into account. This problem is demonstrated with the following example of an aquifer regeneration in a uranium mine. The ore was leached in this mine by in-situ leaching (ISL) using sulfuric acid. The hydrochemical composition of the water that is in the aquifer after this in-situ leaching process is shown as “ISL” in Table 41:

**Table 41 Water analysis of a natural groundwater (GW) and groundwater influenced by in-situ leaching (ISL) (concentrations in mg/L)**

Parameter	GW	ISL	Parameter	GW	ISL	Parameter	GW	ISL
pe	6.08	10.56	Cu	0.005	3	Ni	0.005	5
Temp.	10 °C	10	F	0.5	1	NO <sub>3</sub> <sup>-</sup>	0.5	100
Al	3.0	200	Fe	0.6	600	Pb	0.05	0.2
As	0.004	2	K	1.5	4	pH	6.6	2.3
C(4)	130		Li	0.02	0.1	Si	3.64	50
Ca	36.6	400	Mg	3.5	50	SO <sub>4</sub> <sup>2-</sup>	14.3	5000
Cd	0.0003	1	Mn	0.07	20	U	0.005	40
Cl	2.1	450	Na	5.8	500			

The simulation will be done in a zone of 200 m between an infiltration well and a pumping well. This zone shows a  $k_f$  value of  $5 \cdot 10^{-5}$  m/s along the fracture and  $10^{-8}$  m/s within the pores (those  $k_f$  values are only for orientation and are not needed directly for the modeling). The flow velocity is 10 m/day due to the potential head. The dispersivity is 2 m. Natural groundwater (“GW” in Table 41) will be infiltrated in the infiltration well and extracted at the pumping well.

Assume that the exchange between pores and fractures only takes place by diffusion ( $2 \cdot 10^{-10}$  m<sup>2</sup>/s). The fracture volume is 0.05, and the pore volume is 0.15. Presuppose that the fractures are planar and that the distance between them is 20 cm. Thus, on average each fracture has a pore matrix of 10 cm thickness to each side. Homogeneous and heterogeneous reactions shall be ignored.

The simulation time is supposed to be 200 days. Thus, the water of the fractures will be exchanged 10 times in the 200 m long aquifer section.

The discretisation shall be carried out in elements of 10 m length. The connection of the immobile cells to the mobile cells is done by a box for each cell (Fig. 62) and the exchange between mobile and immobile cells by the means of a 1st order reaction (for theory see chapter 1.3.3.3.1). Present the concentrations of the elements U, Fe, Al, and S at the pumping well over a period of 200 days.

Change the parameter “immobile pore volume” from 0.15 to 0.05 and the matrix thickness on each side of each fracture from 0.1 to 0.01. Compare the results.

Fig. 62 Scheme for the model approach of a double porosity aquifer

### 3.3.6 3D Transport – Uranium and arsenic contamination plume

In the introductory example for 3D transport modeling with PHAST (chapter 2.2.2.5.3), distribution of a uranium contamination from an in-situ leaching mine was modeled. Comparing the concentrations of uranium and arsenic in that example shows a significantly better sorption for arsenic by surface complexation on iron-hydroxides than for uranium. To demonstrate the influence of surface complexation on the contamination plume, change the PHAST input file and/or the PHREEQC control file by removing the calculation for surface complexation. Now you will see a significant change in particular for arsenic. It might be a good idea to copy the \*.phast and the \*.chem.dat file to new filenames before making any changes, since you can then readily compare between different versions.

In a second step, implement an iron permeable reactive barrier (PRB) in the 3D PHAST model! Reactive barriers with zero valent iron are commonly used for natural attenuation remediation measures. Assuming that zero-valent iron is available (which is probably oversimplification) we can model this by implementing a reactive wall 100 m downstream of the mine by using the “new zone” tool: simply draw a rectangular box and adjust it by clicking on the new zone with the red arrow symbol. Zone dimension boxes will open in the lower left corner where you can set x to 100 & 115, y to 100 & 400 and z to 50 & 100. Thus, the new zone (5) and the reactive wall will be only in the upper 30 m.

Additionally, you will have to define EQUILIBRIUM\_PHASES 2 within the WPHAST GUI and you have to adapt the \*.chem.dat file by adding EQUILIBRIUM\_PHASES 2 with iron as phase to be dissolved and uraninite as phase to be precipitated only. Since REACTION is not available in PHAST and iron is not a defined phase in WATEQ4F (which is named PHAST.dat in your case) you have to define zero-valent iron as phase via the keyword PHASES in the input file (HINT: LLNL-database does contain iron as phase).

As a final step, extend now the surface complexation for uranium species. Checking the WATEQ4F database (named phast.dat in this particular case) you will find at the very end of the file the defined surface complexation species. For uranium only  $\text{UO}_2^{2+}$  is defined. At a pH of  $>6$  under natural conditions  $\text{UO}_2$ -carbonate species are dominant, but they are not defined as candidates for surface complexation. Thus, define a surface complexation species for  $\text{UO}_2(\text{CO}_3)_2^-$  in the PHREEQC control file of the PHAST job by adding a SURFACE\_SPECIES block with two weak surface species: SURFACE- $\text{UO}_2(\text{CO}_3)_2^-$  with log\_k of 12.0 and SURFACE- $\text{UO}_2(\text{CO}_3)_2^{2-}$  with log\_k 5.0. Hint: take the sulphate complexation as an example.

# 4 Solutions

## 4.1 Equilibrium reactions

### 4.1.1 Groundwater – Lithosphere

#### 4.1.1.1 Standard output well analysis

The water sample shows a low to average mineralization (ionic strength  $I = 1.189 \times 10^{-2}$  mol/L „description of solution“). It can be classified as Ca-Mg-HCO<sub>3</sub>-type (Ca 1.872 mmol/L, Mg 1.646 mmol/L, HCO<sub>3</sub><sup>-</sup> 3.936 mmol/L; „solution composition“). The analytical accuracy is sufficient with an electrical balance (eq) of  $-3.407 \times 10^{-4}$  and a percent error  $(100 * (Cat - |An|) / (Cat + |An|))$  of -2.36%.

Fig. 63 EXCEL pie chart presenting the species distribution for Ca, Mg, Zn, and Pb

In terms of redox-sensitive elements it is remarkable that for As, Cu, Fe, N, and U the respective oxidized forms predominate, while Mn predominantly occurs as Mn (+2) and Se as Se (+4). Fig. 21 shows that the Mn oxidation does not start up to a pE > +10, while the present analysis has a pE of 6.9. The oxidation of Se starts at

lower values so that Se (-2) is already completely oxidized, and there are small quantities of Se(+6). However, the partly reduced form Se(+4) still predominates.

Fig. 64 EXCEL bar chart presenting the supersaturated aluminum mineral phases

Fig. 65 EXCEL bar chart presenting the supersaturated iron mineral phases

The species distribution of Ca, Mg, Zn, and Pb can be seen in Fig. 63. It is noteworthy that Ca, Mg, and Zn predominantly occur as free ions in contrast to lead, which typically forms complexes. The most important complexing anion for calcium and magnesium is sulfate, for lead and zinc it is hydrogen carbonate.

Fig. 64 and Fig. 65 show the supersaturated Al and Fe mineral phases. As already mentioned in chapter 2.2.2.1.1, the amorphous mineral phases precipitate initially. In this example, it is only  $\text{Fe}(\text{OH})_3(\text{a})$  because  $\text{Al}(\text{OH})_3(\text{a})$  is undersaturated. Because of the low total concentrations of 0.056 mg/L for Al and 0.067 mg/L for Fe, further mineral precipitations are unlikely to occur.

#### ***4.1.1.2 Equilibrium reaction – solubility of gypsum***

Because of its general flow direction from the east to the west the groundwater flows through the gypsum deposit before it enters the planned new well. In contact with the mineral deposit  $1.432\text{e-}02$  mol/L gypsum can dissolve (delta gypsum from the section “phase assemblage”, the minus sign indicates that gypsum dissolves). Thus, the total mineralization increases from  $1.190\text{e-}02$  mol/L in the old well (assumed to be characteristic for this aquifer) to  $4.795\text{e-}02$  mol/L, which is 4 times higher than the initial value. The Ca concentration increases from  $1.872\text{e-}03$  mol/L (75 mg/L) for the old well to  $1.618\text{e-}02$  mol/L (645 mg/L) and the sulfate concentration from  $2.083\text{e-}03$  mol/L (200 mg/L) to  $1.639\text{e-}02$  mol/L (1570 mg/L).

Thus, the drinking water standards of 400 mg/L for Ca and 240 mg/L for  $\text{SO}_4^{2-}$  are exceeded by far. While the level for Ca is of rather technical significance, since high Ca values may lead to calcite precipitation in the pipe system (also see chapter 3.1.5.2), the sulfate standard has a medical background, because sulfate can cause diarrhea in high concentrations.

To calculate the sulfate content, not only the  $\text{SO}_4^{2-}$  ion as listed in the species distribution but all S(6) species were considered. Most analytical methods determine all S(6) compounds as “sulfate” and, moreover, also the drinking water standard refers to this rather “theoretical” total sulfate content.

#### ***4.1.1.3 Disequilibrium reaction – solubility of gypsum***

Assuming an incomplete dissolution of gypsum ( $50\% \rightarrow \log 0.5 = 0.3 \rightarrow \text{EQUILIBRIUM\_PHASES gypsum } 0.3$ ) only  $7.832\text{e-}03$  mol/L of gypsum dissolve. After the reaction, the total mineralization is  $3.259\text{e-}02$  mol/L, the Ca content 388 mg/L, sulfate 950.4 mg/L. Hence, the Ca content is slightly below the standard, while the limit for sulfate is still clearly exceeded. All in all, the planned well location can not be recommended. At least the high sulfate concentrations would make an expensive water treatment indispensable.

#### 4.1.1.4 Temperature dependency of gypsum solubility in well water

The following amounts of gypsum dissolve at the corresponding temperatures:

$\Delta$  gypsum  $-7.217\text{e-}03$  mol/L at  $10^\circ\text{C}$

$\Delta$  gypsum  $-7.736\text{e-}03$  mol/L at  $20^\circ\text{C}$

$\Delta$  gypsum  $-8.074\text{e-}03$  mol/L at  $30^\circ\text{C}$

$\Delta$  gypsum  $-8.229\text{e-}03$  mol/L at  $40^\circ\text{C}$

$\Delta$  gypsum  $-8.213\text{e-}03$  mol/L at  $50^\circ\text{C}$

$\Delta$  gypsum  $-8.047\text{e-}03$  mol/L at  $60^\circ\text{C}$

$\Delta$  gypsum  $-7.753\text{e-}03$  mol/L at  $70^\circ\text{C}$

The maximum solubility of gypsum occurs at  $40^\circ\text{C}$  (Fig. 66). The first increase of solubility with temperature is related to the endothermic formation of the  $\text{CaSO}_4^0$  complex, the significance of which was already shown in the example 2 in chapter 2.2.2.1.2 ( $\Delta H(\text{CaSO}_4^0) = +1.6 \rightarrow \Delta G > 0$ , since  $\Delta G = -R \cdot T \cdot \ln K$  it follows, if  $T \uparrow$   $-\ln K \downarrow$ , thus  $K \uparrow$ ). The solubility of the mineral phase  $\text{CaSO}_4(\text{s})$  on the other hand decreases with increasing temperature (exothermic process) ( $\Delta H(\text{CaSO}_4(\text{s})) = -0.1 \rightarrow \Delta G < 0$ , since  $\Delta G = -R \cdot T \cdot \ln K$  it follows, if  $T \uparrow$   $\ln K \downarrow$ , thus  $K \downarrow$ ). Both effects overlap and lead to the fact that the maximum gypsum solubility occurs at some medium temperature, at which the formation of the  $\text{CaSO}_4^0$  complex is already increased and the decreasing solubility of  $\text{CaSO}_4(\text{s})$  does not predominate yet. As a consequence of the decreasing mineral solution over  $40^\circ\text{C}$ , also the amount of  $\text{CaSO}_4^0$  decreases.

Fig. 66 Temperature dependency of gypsum solubility in well water and in distilled water.

#### 4.1.1.5 Temperature dependency of gypsum solubility in pure water

Compared to well water, distilled water can dissolve more gypsum (Fig. 66), since the initial concentrations of calcium and sulfate are lower.

#### 4.1.1.6 Temperature- and $P(\text{CO}_2)$ -dependent calcite solubility

The optimum calcite solubility occurs at 30°C (Fig. 67), not at the maximum temperature of 40°C (Table 42).

**Table 42** Dependency of calcite solubility on temperature and  $P(\text{CO}_2)$

Temperature [°C]	$\text{CO}_2$ [Vol%]	$P(\text{CO}_2)$	Calcite [mmol/L]
0	0.03	-3.5	1.07
5	0.5	-2.3	-0.08
8	0.9	-2.05	-0.40
15	2	-1.70	-0.83
25	4.5	-1.3	-1.32
30	7	-1.15	-1.46
40	10	-1	-1.34

Different factors have an influence on the calcite solubility. First of all, like for gypsum (chapter 4.1.1.4) the formation of the  $\text{CaCO}_3^0$  complex is endothermic ( $\Delta H(\text{CaCO}_3^0) = +3.5$ ), while the mineral dissolution is exothermic ( $\Delta H(\text{CaCO}_3(\text{s})) = -2.3$ ). Thus, the maximum solubility occurs at some medium temperature, at which the formation of the  $\text{CaCO}_3^0$  complex is already increased and the decreasing solubility of  $\text{CaCO}_3(\text{s})$  does not predominate yet.

Furthermore, calcite solubility does not only depend on temperature but also on  $P(\text{CO}_2)$ .

As can be seen from the equations above, an increase of  $\text{H}^+$ -ions causes a consumption of  $\text{CO}_3^{2-}$  forming the  $\text{HCO}_3^-$  complex. Thereby  $\text{CaCO}_3$  dissolution is increased. An increase in  $\text{H}^+$ -ions can be caused e.g. by acids ( $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ) but also by an increase of  $\text{CO}_2$  concentration, since  $\text{H}^+$  ions form with the dissolution of  $\text{CO}_2$  in water.

Although the immediate dissociation of  $\text{H}_2\text{CO}_3$  to  $\text{H}^+ + \text{HCO}_3^-$  only makes up 1%, subsequent reactions cause a much higher  $\text{CO}_2$  dissolution.

That means, the higher the  $P(\text{CO}_2)$ , the more  $\text{CaCO}_3$  can be dissolved. Yet, the solubility of  $\text{CO}_2$  as gas in water depends on the temperature: The higher the

temperature the lower the gas solubility. Consequently, initially, the calcite solubility increases with temperature due to the endothermic reaction of  $\text{CaCO}_3^0$  complexation, but with increased temperature the exothermic reaction of  $\text{CaCO}_3(\text{s})$  dissolution and the significantly reduced  $\text{CO}_2$  dissolution decrease the total calcite solubility.

#### 4.1.1.7 Calcite precipitation and dolomite dissolution

In the presence of both calcite and dolomite, dolomite dissolves while calcite precipitates (Table 43, Fig. 67), because the solubility-product of  $\text{CaCO}_3$  is exceeded. This process is called incongruent dissolution (see chapter 1.1.4.1.3). The maximum of dissolution/ precipitation shifts to lower temperatures ( $6^\circ\text{--}7^\circ\text{C}$ ).

**Table 43** Dependency of calcite dissolution and dolomite precipitation on temperature

Temperature [ $^\circ\text{C}$ ]	$\text{CO}_2$ [Vol%]	Calcite [mmol/L]	Dolomite [mmol/L]
0	0.03	2.68	-1.11
5	0.5	4.10	-2.90
8	0.9	4.19	-3.17
15	2	3.79	-3.12
25	4.5	3.02	-2.86
30	7	2.60	-2.65
40	10	1.79	-2.00

**Fig. 67** Calcite solubility and incongruent solution calcite-dolomite (calcite – precipitation and dolomite dissolution)

#### 4.1.1.8 Comparison of the calcite solubility in an open and a closed system

At a  $P(\text{CO}_2)$  of 2 vol% the calcite dissolution is lower in the open system (hence the pH value higher) than in the closed system. At 20 vol%  $P(\text{CO}_2)$  it is the other way around, in the open system the calcite dissolution is higher, the pH value is lower (Table 44).

**Table 44** Calcite dissolution in an open and a closed system at  $P(\text{CO}_2) = 2$  vol%, respectively  $P(\text{CO}_2) = 20$  vol%

	2 Vol% open system	2 Vol% closed system	20 Vol% open system	20 Vol% closed system
pH	7.144	7.028	6.485	6.594
Calcite [mmol/L]	-0.8290	-1.250	-4.385	-3.552

The explanation can be found by modeling the well analysis without any equilibrium reactions. The well sample itself already has a  $\text{CO}_2$  partial pressure of 3.98 vol% (under „initial solution“ - „saturation indices“  $\text{SI } \text{CO}_2(\text{g}) = -1.40 \rightarrow P(\text{CO}_2) = 3.98$  vol%), i.e. the following processes occur in the open and the closed system:

in the open system: a complete gas exchange is possible:

2 vol% complete degassing from 3.98 vol% to 2 vol%

20 vol% complete dissolution from 3.98 vol% to 20 vol%

in the closed system: the gas exchange is suppressed (ideally no exchange at all)

2 vol% minor degassing from 3.98 vol% to 3.02 vol% ( $\text{SI} = -1.52$  for  $\text{CO}_2(\text{g})$  under „batch reaction calculations“ - „saturation indices“  $\rightarrow P(\text{CO}_2) = 3.02$  vol%), since only a limited amount of gas (1 liter) is assumed for the reaction. Because in the open system the partial pressure  $P(\text{CO}_2) = 2$  vol% is lower than in the closed system (3.02 vol%), the calcite dissolution is less.

20 vol% minor dissolution from 3.89 vol% to 13.49 vol% ( $\text{SI} = -0.87$  for  $\text{CO}_2(\text{g})$  under „batch reaction calculations“ - „saturation indices“  $\rightarrow P(\text{CO}_2) = 13.49$  vol%)), since only a limited amount of gas (1 liter) is assumed for the reaction. Therefore, in the open system the  $\text{CO}_2$  partial pressure is higher (20 vol%) than in the closed system (13.49 vol%), and, consequently, the calcite dissolution is higher, too.

#### 4.1.1.9 Pyrite weathering

As can be seen from Fig. 68, with increasing oxygen the pyrite weathering has a crucial influence on the concentrations of  $\text{Fe}^{2+}$  and  $\text{SO}_4^{2-}$ , which increase from 0.001 mol/L to 1 mol/L  $\text{O}_2$  by about 3 orders of magnitude. The pH value drops significantly from 6.3 to 0.7. The resulting water is extremely acid.

In the presence of calcite, the total concentration of  $\text{SO}_4^{2-}$  at oxygen concentrations exceeding 0.05 mol/L strongly increases compared to the pyrite

weathering in the absence of calcite. The reason for this increase is that  $\text{H}^+$  ions are consumed for the formation of the  $\text{HCO}_3^-$  complex, which results from calcite dissolution. This consumption of  $\text{H}^+$  reduces the formation of the  $\text{HSO}_4^-$  complex, and the formation of  $\text{SO}_4^{2-}$  is increased. The  $\text{Fe}^{2+}$  concentration on the other hand decreases. Significant amounts of  $\text{Fe}^{2+}$  are bound in the  $\text{FeHCO}_3^+$ -complex due to higher concentrations of  $\text{HCO}_3^-$  in the presence of calcite. Most important, however, is the influence of calcite on the pH value, which is decreasing from 6.9 to 5.1 only. The presence of calcite causes a significant buffering of the waters formed during pyrite weathering.

In the presence of the mineral phase  $\text{U}_3\text{O}_8$ ,  $5.32 \cdot 10^{-8}$  mol/L and  $1.98 \cdot 10^{-1}$  mol/L uranium can dissolve at 0.001 mol/L  $\text{O}_2$  and 1 mol/L  $\text{O}_2$  respectively (Fig. 69). In the absence of calcite, the pH drops from 6.3 to 2.0. In the presence of calcite the pH value is buffered as in the example described above (6.9 to 5.1). Up to an oxygen concentration of 0.005 mol/L the uranium solubility in the presence of calcite is higher than in its absence because more uranium carbonate complexes can form. However, at higher oxygen contents, the uranium solubility in the presence of calcite is significantly restricted. It reaches  $3.56 \cdot 10^{-6}$  mol/L at 1 mol/L  $\text{O}_2$ , hence only one hundred thousandth of the amount that is soluble in the absence of calcite. Thus, calcite effectively contributes to the reduction of uranium concentrations in the groundwater during pyrite weathering.

Fig. 68 Effects of pyrite weathering on the concentrations of  $\text{Fe}^{2+}$ ,  $\text{SO}_4^{2-}$  and  $\text{H}^+$  in the absence and in the presence of calcite

Fig. 69 Effects of pyrite weathering in the presence of the mineral phase  $\text{U}_3\text{O}_8$  on the concentrations of uranium and  $\text{H}^+$  in the absence and in the presence of calcite (y-axis logarithmic).

#### 4.1.2 Atmosphere – Groundwater – Lithosphere

##### 4.1.2.1 Precipitation under the influence of soil $\text{CO}_2$

The increased soil  $\text{CO}_2$  partial pressure of 1 vol% - compared to atmospheric  $\text{P}(\text{CO}_2) = 0.03$  vol% - causes an increase in the concentration of the  $\text{H}^+$  ions (see chapter 3.1.1.6). Thus, the pH value of the rainwater decreases from 5.1 to 4.775, while at the same time the concentration of dissolved carbon increases from 13  $\mu\text{mol/L}$  to 390  $\mu\text{mol/L}$ .

##### 4.1.2.2 Buffering systems in the soil

The pH value of the infiltrating rainwater under increased  $\text{CO}_2$  partial pressures in the soil is 4.775. In this pH range the iron hydroxide buffer shows no effect at all. The pH value remains at 4.775 even after the reaction with goethite. Iron buffers only play a role for reactions in very acid mine waters (pH 2 to 4), by the transformation of goethite into Fe (III) under proton consumption:  $\text{FeOOH} + 3\text{H}^+ = \text{Fe}^{3+} + 2\text{H}_2\text{O}$ . The reaction with aluminum hydroxide (boehmite  $\text{AlOOH} + \text{H}_2\text{O} + 3\text{H}^+ = \text{Al}^{3+} + 3\text{H}_2\text{O}$ ) shows little buffering capacity. The pH is 4.91 after the reaction. Similarly, manganese hydroxides ( $\text{MnOOH} + 3\text{H}^+ + \text{e}^- = \text{Mn}^{2+} + 2\text{H}_2\text{O}$ ) buffers only slightly from pH 4.775 to 5.032. In the exchanger buffering system the protons are sorbed on the exchanger while (earth) alkaline ions are released.

The buffered pH value is 6.718 and thus almost in the neutral pH range. The most effective buffer is the carbonate buffer, which is responsible for buffering most of the systems in the pH range of 5.5 to 8.0. After the reaction with calcite, the pH of rainwater increases from 4.775 to 7.294.

Because of the slow kinetics of feldspar weathering, the modeling of a silicate buffer is impossible by equilibrium reactions only. Kinetics must be considered, which will not be done here.

#### 4.1.2.3 Mineral precipitations at hot sulfur springs

At 45°C a maximum of about 6.5 mg O<sub>2</sub> can dissolve in one liter of water. The gas solubilities given in Table 45 first must be recalculated to the respective temperatures (T), for 0 °C e.g.:

0.0473 cm<sup>3</sup> water/cm<sup>3</sup> water = 0.0473 L gas/L water;

since 22.4 L = 1 mol gas: 0.0473 : 22.4 mol gas/L water =  $2.11 \cdot 10^{-3}$  mol/L

since the mole mass of O<sub>2</sub> = 32 g/mol:  $2.11 \cdot 10^{-3}$  mol/L · 32 g/mol = 0.0676 g/L = 67.6 mg/L

The calculated value would be correct for 100 vol% O<sub>2</sub>. However, there are only 21 vol% in the atmosphere. Thus, 67.6 mg/L must be multiplied by 0.21 to get 14.19 mg/L O<sub>2</sub>-solubility at 0°C.

**Table 45** Dependency of O<sub>2</sub> solubilities on temperature at P(O<sub>2</sub>) = 21 vol%

T	Gas solubility [cm <sup>3</sup> /cm <sup>3</sup> ]	Gas solubility [mg/L]	T	Gas solubility [cm <sup>3</sup> /cm <sup>3</sup> ]	Gas solubility [mg/L]	T	Gas solubility [cm <sup>3</sup> /cm <sup>3</sup> ]	Gas solubility [mg/L]
0	0.0473	14.19	20	0.0300	9.00	50	0.0204	6.12
5	0.0415	12.45	25	0.0275	8.25	60	0.0190	5.70
10	0.0368	11.04	30	0.0250	7.50	70	0.0181	5.43
15	0.0330	9.90	40	0.0225	6.75	90	0.0172	5.16

Thus, using REACTION 1, 2, 3, 4, 5, 6, and 6.5 mg/L O<sub>2</sub> (converted into mol/L) are added. For CO<sub>2</sub>, equilibrium with the atmospheric partial pressure can be defined simply by using the keyword EQUILIBRIUM\_PHASES, since all the subsequent reactions depend only on the diffusion of the CO<sub>2</sub> and its dissociation in water. Contrary to redox reactions with oxygen both processes are fast reactions, hence can be described by equilibrium reactions, neglecting kinetics.

As long as sulfur-rich thermal waters circulate in the underground, all mineral phases except for the Si compounds are undersaturated. Upon discharge as spring water, the exposure to a small quantity of oxygen is sufficient to reach a supersaturation with regard to elemental sulfur (SI = 0.04 at 1 mg O<sub>2</sub>/L to SI = 0.47 at 6.5 mg O<sub>2</sub>/L). Even at higher O<sub>2</sub> contents, gypsum stays undersaturated (SI = -6.6 at 1 mg O<sub>2</sub>/L to -3.25 at 6.5 mg O<sub>2</sub>/L). Close to the spring's discharge the supersaturated sulfur precipitates spontaneously together with SiO<sub>2</sub>(a) forming the characteristic yellow – red sulfur sinter incrustations. Depending on the O<sub>2</sub> content

the amount of precipitating sulfur varies from 0.419 mg S/L to 11.26 mg S/L at maximum  $O_2$  - solubility.

#### 4.1.2.4 Formation of stalactites in karst caves

The rainwater infiltrates in the soil of the karst area. Under the increased  $CO_2$  partial pressure of 3 vol% in the soil the dissolution of 2.613 mmol/L calcite (simulation1/batch reactions/phase assemblage) occurs and karst cavities form. From the cave ceilings, water saturated with regard to calcite drips. As soon as the infiltrating water creates a karst drainage system, which finally discharges to a river, the  $CO_2$  content drops to the level of atmospheric partial pressure (0.03 vol%). With decreasing  $P(CO_2)$ , calcite precipitation inevitably results (see also chapter 3.1.1.6), leading to the precipitation of 2.116 mmol/L (simulation2/batch reactions/phase assemblage) or 211.6 mg/L  $CaCO_3$  (2.116 mmol/L · mole mass 100 mg/mmol = 211.6 mg/L). Assuming a daily amount of 100 liter of water dripping from the cave's ceiling, that amounts to 211.6 mg/L · 100 L/d = 21.16 g/d, or for one year (365 day) about 7.7 kg/a.

Taking 2.71 g/cm<sup>3</sup> as density, a precipitated volume of calcite of 7.7 kg/a : 2.71 kg/dm<sup>3</sup> = 2.84 dm<sup>3</sup>/a results. Because only about 15% of the ceiling of the karst cave is covered by stalactites, this volume is spread on 0.15 · 10 m (length) · 10 m (width) = 15 m<sup>2</sup>. Thus the stalactites grow by 2.84 dm<sup>3</sup>/a : 15 : 10<sup>2</sup> dm<sup>2</sup> = 0.0019 dm/a = 0.19 mm/a.

#### 4.1.2.5 Evaporation

The negative amount of water, which must be used for titration, equals 54.38 moles. The rainfall of 250 mm must be reduced by 20 mm for the runoff, which leaves 230 mm for infiltration. That comes up with 225 mm evaporation/230 mm infiltration = 98 % of evaporation; this means that 98% of the amount of water (pure  $H_2O$  without any ions) must be removed (98% of 55.5 moles = 54.38 moles). That leaves 2% of highly concentrated solution, which must be multiplied 50 times by itself to get back to 100% of highly concentrated solution (50 · 2% = 100%). Additionally, equilibrium with calcite, quartz, and 0.01 bar of  $CO_2$  ( $CO_2(g)$  -2.0) must be adjusted.

This calculation results in the solution composition shown in Table 46 with and without consideration of evaporation (in mol/L).

Considering evaporation, the elements Cl, K, Mg, N(5), Na, and S(6) yield a concentration about 35 times higher than without considering evaporation. For Ca, Si, and  $HCO_3$  the difference is smaller, since for those elements an additional input - independent of the evaporation - is assumed by the equilibrium reactions in the underground. The increase in the gypsum saturation index is remarkable, showing that at high evaporation rates even gypsum precipitation might occur.

**Table 46 Groundwater recharge with and without consideration of evaporation**

Groundwater recharge without consideration of evaporation		Groundwater recharge with consideration of evaporation	
C	3.85e-03 mol/L	C	3.11e-03 mol/L
Ca	1.84e-03 mol/L	Ca	4.61e-03 mol/L
Cl	2.30e-05 mol/L	Cl	7.95e-04 mol/L
K	7.00e-06 mol/L	K	2.42e-04 mol/L
Mg	2.90e-05 mol/L	Mg	1.00e-03 mol/L
N(5)	8.00e-05 mol/L	N(5)	2.77e-03 mol/L
Na	8.00e-06 mol/L	Na	2.77e-04 mol/L
S(6)	8.20e-05 mol/L	S(6)	2.83e-03 mol/L
Si	9.13e-05 mol/L	Si	9.10e-05 mol/L
pH = 7.294		pH = 7.161	
SI (gypsum) = -2.60		SI (gypsum) = -0.93	

Under PHASE ASSEMBLAGE one can find the amount of calcite dissolved (- 2.169 mmol/L, respectively  $2.169/L \cdot 100 \text{ mg/mmol} = 216.9 \text{ mg/L}$ ). The groundwater recharge can be calculated from 5 mm/a (250 mm rainfall - 20 mm runoff - 225 mm evaporation) related to the recharge area of 50 km · 30 km to  $5 \text{ mm/a} \cdot 1500 \text{ km}^2 = 0.005 \text{ m/a} \cdot 1.5 \cdot 10^9 \text{ m}^2 = 7.5 \cdot 10^6 \text{ m}^3/\text{a}$  or  $7.5 \cdot 10^9 \text{ L/a}$ . For this groundwater recharge, a dissolved amount of calcite of  $216.9 \text{ mg/L} \cdot 7.5 \cdot 10^9 \text{ L/a} = 1.627 \cdot 10^{12} \text{ mg/a} = 1627 \text{ t/a}$  results.

For a calcite density of  $2.71 \text{ g/dm}^3$  that amounts to a cavity volume of  $1627 \text{ t/a} : 2.71 \cdot 10^{-6} \text{ t/dm}^3 = 6.0 \cdot 10^8 \text{ dm}^3/\text{a}$  or  $6.0 \cdot 10^5 \text{ m}^3/\text{a}$ . Recalculated to an area of 50 km · 30 km, a subsidence of  $6.0 \cdot 10^5 \text{ m}^3/\text{a} : (50 \text{ km} \cdot 30 \text{ km}) = 6.0 \cdot 10^5 \text{ m}^3/\text{a} : 1.5 \cdot 10^9 \text{ m}^2 = 4.0 \cdot 10^{-4} \text{ m/a} = 0.4 \text{ mm/a}$  can be calculated.

### 4.1.3 Groundwater

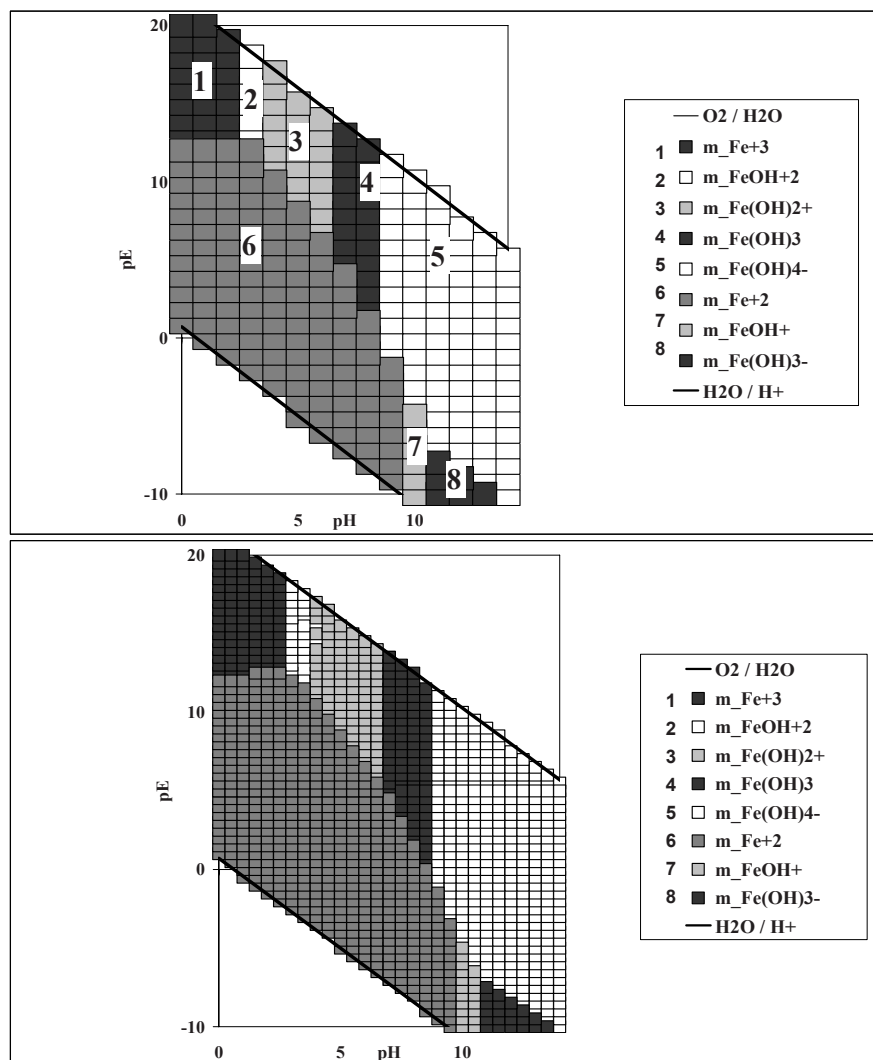

#### 4.1.3.1 The pE-pH diagram for the system iron

The following species must be defined within the keyword SELECTED\_OUTPUT to assess whether they predominate and if so, under which pH-pE-conditions:  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$ ,  $\text{FeCl}^+$ ,  $\text{FeOH}^+$ ,  $\text{Fe(OH)}_2$ ,  $\text{Fe(OH)}_3^-$ ,  $\text{Fe(OH)}_2^+$ ,  $\text{Fe(OH)}_3$ ,  $\text{FeOH}^{2+}$ ,  $\text{Fe}_2(\text{OH})_2^{4+}$ ,  $\text{Fe(OH)}_4^-$ ,  $\text{Fe}_3(\text{OH})_4^{5+}$ ,  $\text{FeCl}_2^+$ ,  $\text{FeCl}^{2+}$ ,  $\text{FeCl}_3$ .

Fig. 70 shows the predominance diagram as a result of the modeling. The second raster, created by the 4-fold number of data by cutting down the step width by half, reveals a higher resolution. However, no additional species appear, that might have been missed by the lower resolution in the first raster. The gaps within the 0.5-step raster at the pH-pE combinations of pH 3.5/pE 12.5, pH 3.5/pE 13, pH 4/pE 14.5, pH 4/pE 15.5 and pH 3.5/pE 16 arise from numerical problems that occurred during the modeling and allowed no convergence of the model. The corresponding SOLUTIONS were removed from the PHREEQC input file.

Comparing the created pE-pH diagram to the one for the system Fe-O<sub>2</sub>- H<sub>2</sub>O according to Langmuir (1997; Fig. 16), clear similarities can be shown. Just the

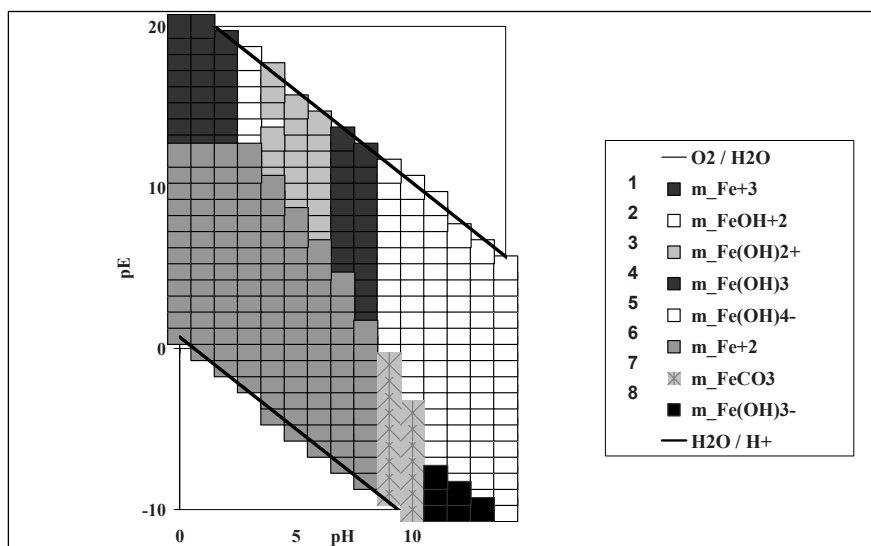

$\text{Fe}(\text{OH})_3^-$ -field is somewhat smaller in the example and an additional field for the  $\text{FeOH}^+$  species is indicated, which is lacking in the diagram of Langmuir (1997).

**Fig. 70** pE-pH diagram for the system iron (initial solution 10 mmol Fe + 10mmol Cl); Variation of pE, pH in steps of 1 (above) and 0.5 (below, higher raster resolution, numbers as indicated in the figure above)

### 4.1.3.2 The Fe pE-pH diagram considering carbon and sulfur

In SELECTED OUTPUT  $\text{FeHCO}_3^+$ , and  $\text{FeCO}_3$  for the iron - carbon system as well as  $\text{FeSO}_4^+$ ,  $\text{FeHSO}_4^{2+}$ ,  $\text{Fe}(\text{SO}_4)_2^-$ ,  $\text{FeHSO}_4^+$ , and  $\text{FeSO}_4$  for the iron - sulfur system must be defined for the output besides the iron species from chapter 4.1.3.1. For both systems numerical problems occur at pH 4 and pH 14.

**Fig. 71** pE-pH-diagram for the system iron-carbon (initial solution 10 mmol Fe + 10 mmol Cl + 10 mmol C), numbers as indicated in Fig. 70

In the iron - carbon system (Fig. 71) the  $\text{FeOH}^+$  - field vanishes, the zero-charged  $\text{FeCO}_3^0$  - field predominates instead under the same pE - pH conditions. In the iron - sulfur system (Fig. 72) the predominance field of the iron - sulfate species  $\text{FeSO}_4^+$  enlarges at the expense of  $\text{Fe}^{3+}$ , while  $\text{FeOH}^{2+}$  disappears completely.

The pE-pH diagrams, as the ones modeled and presented in Fig. 70 to Fig. 72, provide a good overview of possible predominating species. However, they have the significant disadvantage that for setting up a complete diagram covering all ranges (i.e. from extremely oxidizing to extremely reducing, and from extremely acid to extremely alkaline) only idealized solutions can be modeled. Those idealized solutions contain only few defined species, as e.g. in the example, only C or S apart from Fe and Cl as the corresponding anion. The ion balance frequently shows larger deviations than 2%. The requirement of a constant ionic strength through all pE - pH fields can only be partially maintained. Moreover, species that occur in almost the same concentration as the predominating species, and are possibly significant for reactive transport, are totally neglected in predominance diagrams. These weaknesses of pE - pH diagrams must be kept in mind for modeling and interpretation.

Fig. 72 pE-pH diagram for the system iron – sulfur [initial solution 10 mmol Fe + 10 mmol Cl + 10 mmol C], numbers as indicated in Fig. 70

#### 4.1.3.3 The pH dependency of uranium species

First of all, both solutions, the acid mine water and the groundwater, are defined in the PHREEQC input file and mixed applying the keyword MIX. Then this solution is saved as solution 3 (SAVE\_SOLUTION) and the job is finished by END. A second job follows, which uses again SOLUTION 2 (groundwater) and SOLUTION 3 (1:1 diluted water) via the keyword USE, mixes both solutions 1:1, and saves the result as SOLUTION 4, etc. SELECTED\_OUTPUT facilitates the further data processing in EXCEL by providing the pH values and the “molalities” of all uranium species. The keyword itself has to be repeated for every job, as well as the definition of the desired parameters pH and molalities. Yet the file name (e.g. 3\_uranium\_species\_pHdependent.csv) should only appear within the first SELECTED\_OUTPUT block and not be repeated. This way PHREEQC writes the parameters of all modeling steps in one single SELECTED\_OUTPUT file. The headline, however, is repeated for every modeling run. The sub keyword “- reset false”, also applied just once within the first SELECTED\_OUTPUT block, suppresses the standard output for all other modeling, which are written into the same file.

With seven mixings plus the initial solution of acid mine water and the resulting solution of groundwater the variations in uranium species are as shown in (Fig. 73).

**Fig. 73** Development of uranium species during the mixing of an acid mine water (pH= 2.3) with a groundwater (pH=6.6)

For low pH values the zero-charged  $\text{UO}_2\text{SO}_4^0$  complex predominates. The positively charged  $\text{UO}_2^{2+}$  complex reaches similar concentrations though. From pH=5 on, the carbonate complexes predominate, first the zero-charged  $\text{UO}_2\text{CO}_3^0$  complex, at pH values exceeding 6 the negatively charged  $\text{UO}_2(\text{CO}_3)_2^{2-}$  complex. Both carbonate complexes are of no importance in an acid environment (pH values < 3.5). For transport and sorption processes, especially the zero-charged complexes have to be taken into account, since they show only little interactions, hence can hardly be retarded.

#### 4.1.4 Origin of groundwater

##### 4.1.4.1 Pumping of fossil groundwater in arid regions

The mineral phases calcite, dolomite, halite, and gypsum for the Cretaceous limestone, as well as albite, quartz, anorthite, K-mica for the sandstone, and the gaseous phase  $\text{CO}_2$  have to be defined. Furthermore it is assumed that dolomite, gypsum, and halite only dissolve, while calcite precipitates and  $\text{CO}_2$  degasses. Under those conditions and with an uncertainty of 4%, two models are obtained (Table 47).

Both models differ only slightly; model 2 does not use quartz as a mineral phase. The ratio fossil to recent groundwater is equal for both models: 62%:38%, which means that almost two thirds of the extracted groundwater is not recharged. With a pumping rate of 50 L/s or  $50 \cdot 60 \cdot 60 \cdot 24 \text{ L/d} = 4,320,000 \text{ L/d}$ ,  $0.6211 \cdot 4,320,000 \text{ L/d} = 2,683,152 \text{ L/d}$  fossil water are extracted. For a reservoir of 5 m ·

$1000 \text{ m} \cdot 10,000 \text{ m} = 50,000,000 \text{ m}^3$  or  $50,000,000,000 \text{ L}$  it takes  $50,000,000,000 \text{ L} : 2,683,152 \text{ L/d} = 18635 \text{ d}$  or  $18635 \text{ d} : 365 =$  approximately 51 years until the reservoir is completely exploited, and only recent groundwater is available anymore. Thus, assuming a constant supply, this amount will be only 38% of the present production, i.e. 19 L/s instead of 50 L/s, which are also subject to larger variations independent of the rainfall.

**Table 47** Two models, showing the share of fossil groundwater compared to recent groundwater in an arid region (precipitating mineral phases +, dissolving mineral phases -, concentration in mol/L)

Isotopic composition of phases	Model 1		Model 2	
13C Calcite	2 + -2 = 0		2 + -2 = 0	
13C CO <sub>2</sub> (g)	-25 + -5 = -30		-25 + -5 = -30	
Solution fractions	share	percentage	share	percentage
Solution 1 (fossil water)	6.21E-01	62.11	6.21E-01	62.11
Solution 2 (recent groundwater)	3.79E-01	37.89	3.79E-01	37.89
Solution 3	1.00E+00	100.00	1.00E+00	
Phase mole transfers				
Calcite CaCO <sub>3</sub>	-2.59E-04	pre	-2.59E-04	pre
CO <sub>2</sub> (g)	-2.48E-04	pre	-2.48E-04	pre

Anorthite CaAl <sub>2</sub> Si <sub>2</sub> O <sub>8</sub>	1.16E-04	dis	1.14E-04	dis
Gypsum CaSO <sub>4</sub>	2.80E-04	dis	2.82E-04	dis

#### 4.1.4.2 Salt water/fresh water interface

Just as with every task of inverse modeling there is not one correct solution, but a number of possible solutions. First, by means of the sub keyword “charge” the electrical balance must be corrected because the analytic error is too high with - 4.65%. The best way is to use calcium to attain a balanced charge.

**Table 48** Three models for the determination of the proportion of sea water relative to fresh water in the irrigation water (precipitating mineral phases +, dissolving mineral phases -, concentration in mol/L)

Model 1		Model 2		Model 3	
CO <sub>2</sub> (g)	4.91E-04	CO <sub>2</sub> (g)	4.93E-04	CO <sub>2</sub> (g)	4.93E-04
Gypsum	1.25E-04	Gypsum	1.28E-04	Gypsum	1.28E-04
Quartz	9.79E-06	Calcite	-2.00E-04	Quartz	-9.71E-08
K-Mica	1.65E-06	Dolomite	-1.16E-04	Calcite	-2.00E-04
Albite	-4.94E-06			Dolomite	-1.16E-04
Calcite	-1.97E-04				
Dolomite	-1.17E-04				

With a very small uncertainty of 0.006 for the gaseous phase  $\text{CO}_2$ , the mineral phases gypsum and halite (for the marine environment), quartz, K-mica, albite, and anorthite (from the Quaternary aquifer) as well as calcite and dolomite (from the Cretaceous limestone) and assuming that halite, gypsum, K-mica, albite, and anorthite can only be dissolved, the following three models were found (Table 48). Since quartz, feldspar and mica are considered as significant mineral phases in the Quaternary aquifer and these are only represented in the first model, this one is chosen. Independent of that, the proportion of seawater to groundwater is 22.55% to 77.45% in all three models.

#### 4.1.5 Anthropogenic use of groundwater

##### 4.1.5.1 Sampling: Ca titration with EDTA

In order to get the sample alkaline first, 0.1 mol NaOH is added using the keyword REACTION. This addition causes an increase in pH value from 6.7 to 13.343. This alkaline solution is saved, and recalled in a second job. Using REACTION, EDTA is added (for this example 1e-5, 5e-5, 1e-4, 5e-4, 1e-3, 5e-3, 1e-2, 5e-2, 1e-1, 5e-1, 1, 5 and 10 mol/L).

Fig. 74 shows the predominant Ca-complexes at the described conditions.

**Fig. 74** Stability of the Ca-EDTA complex upon addition of 5e-3 to 1e-2 mol/L EDTA to a solution, which is alkalized with 0.1 mol NaOH to a pH of 13.34; larger amounts of EDTA in solution lead to deprotonization and thus to a decrease in pH value, EDTA is preferably bound to  $\text{H}^+$  ions, the  $\text{CaEdta}^{2-}$  complex loses significance.

Upon addition of small quantities of EDTA to the alkaline solution, free  $\text{Ca}^{2+}$  cations and the Ca-hydroxo complex  $\text{CaOH}^+$  predominate. From about 0.5 to 1

mmol/L EDTA the  $\text{Ca-EDTA}^{2-}$  complex gains significance. Between 5 to 10 mmol/L EDTA at last all Ca is bound as  $\text{Ca-Edta}^{2-}$  complex and is determined by means of a color indicator. If more than 10 mmol/L of EDTA are added, the pH drops immediately from 13 to about 3, since the deprotonization of the acid EDTA exceeds the alkaline buffering with NaOH. Preferably  $\text{H}^+$ -EDTA-complexes form ( $\text{EdtaH}_2^{2-}$ ,  $\text{EdtaH}_3^-$ , etc.). For Ca only a limited amount of EDTA is available. The  $\text{CaHedta}^-$  complex and again free  $\text{Ca}^{2+}$ -cations predominate.

Using 1 mol NaOH instead of 0.1 mol in the beginning of the titration the stability range of the  $\text{Ca-Edta}^{2-}$  complex enlarges. Using 0.01 mol NaOH,  $\text{Ca-Edta}^{2-}$  does not predominate in any range anymore.

#### 4.1.5.2 Carbonic acid aggressiveness

Considering calcite equilibrium, a pHc of 7.076 results which is 0.376 pH units above the measured pH value of 6.7. The permitted deviation of 0.2 is exceeded. Since pH-pHc is negative, the water is calcite aggressive, i.e., it can still dissolve calcite and has potential for pipe corrosion. Undersaturation can also be determined without calculation of the pHc, because within “initial solution calculations” in the PHREEQC output, calcite already shows a saturation index of -0.63 (= 23% saturation).

#### 4.1.5.3 Water treatment by aeration – well water

After aeration by adjustment of an equilibrium with the atmospheric  $\text{CO}_2$  partial pressure (0.03 Vol%,  $\text{CO}_2(\text{g})$  -3.52) the pH value increases to 8.783, the pHc to 7.57. Thus  $\Delta\text{pH}$  is +1.213, i.e., the water is supersaturated with regard to calcite and calcite precipitation might occur in the pipe systems. The SI calcite (under “batch reaction calculations”) is +1.35. Thus, aeration deteriorates the initial conditions regarding calcite equilibrium. The drinking water standards are exceeded by far.

#### 4.1.5.4 Water treatment by aeration – sulfur spring

The species distribution of Al, Fe(II), and Fe(III) is depicted in Fig. 75. Al(III) and Fe(II) predominate as OH-complexes. There are almost no free  $\text{Al}^{3+}$  or  $\text{Fe}^{3+}$  cations, while the majority of Fe(II) occurs as free cations (71%), followed by the  $\text{FeHCO}_3^+$  complex (21%). Considering the total iron content, the concentration of Fe(II) ( $4.44 \cdot 10^{-6}$  mol/L) is significantly higher than Fe(III) ( $5.69 \cdot 10^{-15}$  mol/L).

After aeration there are no significant species changes (Fig. 76), beside the fact that the  $\text{Fe}^{\text{II}}(\text{HS})_2$  complex is not formed under oxidizing conditions anymore. Iron is almost completely oxidized to Fe(III) ( $4.44 \cdot 10^{-6}$  mol/L compared to  $1.41 \cdot 10^{-14}$  mol/L for Fe(II)).  $\text{Al}(\text{OH})_3(\text{a})$  and  $\text{Fe}(\text{OH})_3(\text{a})$  are precipitating mineral phases, possibly also some more.

Fig. 75 Al-, Fe(II)- and Fe(III) species distribution prior to aeration

Fig. 76 Al-, Fe(II)- and Fe(III) species distribution after aeration

Variation of the oxygen partial pressure scarcely leads to any changes because in an open system under steady state conditions any amount of oxygen can be dissolved. Hence, all species can be oxidized almost independent of the partial pressure. The concentration of Fe(III) does not change at all, while slight changes

occur for Fe(II). For  $P(\text{O}_2) = 1 \text{ Vol\%}$  Fe (II) is at  $3.019 \cdot 10^{-14} \text{ mol/L}$  and for  $P(\text{O}_2) = 100 \text{ Vol\%}$  at  $9.547 \cdot 10^{-15} \text{ mol/L}$ .

The pH value of 6.462 after aeration is too low according to the drinking water standards. Further water treatment is required.

The amounts of the precipitating mineral phases  $\text{Al}(\text{OH})_3(\text{a})$  and  $\text{Fe}(\text{OH})_3(\text{a})$  can be found under “phase assemblage”. Multiplying these concentrations (in mol/L) with the molecular weight in g/mol and the production rate of the waterworks (in L/s) one gets a concentration (in g/s), which in turn can be transformed into kg/d (Table 49).

**Table 49 Accumulating amounts of sludge resulting from the precipitation of  $\text{Al}(\text{OH})_3$  and  $\text{Fe}(\text{OH})_3$**

	mol/L	mole mass	yield	kg/day
$\text{Al}(\text{OH})_3(\text{a})$	$6.139 \cdot 10^{-6}$	78	30 L/s	1.24
$\text{Fe}(\text{OH})_3(\text{a})$	$4.425 \cdot 10^{-6}$	106.8		1.22

The amount of sludge, resulting from precipitation of Al- and Fe-hydroxides, sums up to 2.46 kg/d of dry mineral phases. Considering the high content of water in the sludge yields a factor of 2.5 (for 60% water content) to 10 (for 90% water content) and an amount of sludge of 6.15 kg/d or 24.6 kg/d, or about 185 - 740 kg/month.

In the simulation, N and S are completely oxidized, which is not necessarily true for a water treatment plant, since redox reactions show appreciable kinetics (slow reactions). Partly reduced forms may persist metastable over long periods of time.

#### 4.1.5.5 Mixing of waters

In the abandoned well  $\text{SO}_4^{2-}$  with 260 mg/L and  $\text{NO}_3^-$  with 70 mg/L exceed the drinking water standards of 240 mg/L and 50 mg/L respectively. In the well currently used there are problems concerning the calcite aggressiveness, as modeled in chapter 3.1.5.2. Therefore these parameters must be taken into account while modeling the mixing of the two waters. The following values were obtained (Table 50).

**Table 50 pH, pHc,  $\text{SO}_4^{2-}$  and  $\text{NO}_3^-$  concentrations for different mixing ratios between the water from the abandoned (old) and the current (new) well**

new : old	pH	pHc	$\Delta\text{pH}$	$\text{SO}_4^{2-}$ [mmol/L]	$\text{SO}_4^{2-}$ [mg/L]	$\text{NO}_3^-$ [mmol/L]	$\text{NO}_3^-$ [mg/L]
0:100	6.99	6.84	0.15	2.707	<b>260.00</b>	1.129	<b>70.01</b>
10:90	6.95	6.86	0.09	2.644	<b>253.95</b>	1.019	<b>63.18</b>
20:80	6.91	6.87	0.04	2.582	<b>248.00</b>	0.908	<b>56.33</b>
30:70	6.87	6.89	-0.02	2.520	<b>242.04</b>	0.798	49.50
40:60	6.84	6.91	-0.07	2.457	235.99	0.688	42.67

50:50	6.81	6.93	-0.12	2.395	230.03	0.577	35.78
60:40	6.79	6.95	-0.16	2.333	224.08	0.467	28.95
70:30	6.76	6.98	<b>-0.22</b>	2.270	218.03	0.356	22.05
80:20	6.74	7.01	<b>-0.27</b>	2.208	212.07	0.246	15.28
90:10	6.72	7.04	<b>-0.32</b>	2.146	206.12	0.136	8.45
100:0	6.70	7.08	<b>-0.38</b>	2.083	200.07	0.024	1.50

If the proportion of the water from the old well is too high, the mixed water shows sulfate and nitrate concentrations exceeding drinking water standards (bold), if it is too low, the mixture is calcite aggressive (bold), which may lead to pipe corrosion. The optimum ratio is between 40 : 60 to 60:40, where the water can be discharged to the drinking water distribution network without further treatment.

#### 4.1.6 Rehabilitation of groundwater

##### 4.1.6.1 Reduction of nitrate with methanol

To determine the amount of methanol required to reduce the nitrate, one has to proceed iteratively, i.e. a certain amount of methanol is added step by step using the keyword REACTION (e.g. 0.1 1 5 10 50 100 mmol/L) and according to the results the step width is refined. In this example a higher resolution was chosen between 1.3 and 1.35 mmol/L. The following result is obtained (Fig. 77).

Fig. 77 Successive reduction of penta-valent  $\text{NO}_3^-$  in an aquifer into zero valent  $\text{N}_2$  and -3-valent  $\text{NH}_4^+$  by addition of methanol (the species  $\text{NO}_2^-$ ,  $\text{NH}_4\text{SO}_4^-$ ,  $\text{NH}_3$  occur in trace amounts only)

Already upon addition of small amounts of methanol (<1 mmol/L) a significant decomposition of  $\text{NO}_3$  to  $\text{N}_2$  occurs, the pE being in the oxidizing range (12 to 14). With 1.345 mmol/L methanol, the nitrate concentration decreases from 1.614 mmol/L to 0.155  $\mu\text{mol/L}$   $\text{N(5)}$  by more than 4 orders of magnitude. If the addition is further increased, the pE value drops notably (pE approx. -2) and  $\text{N}_2$  is further reduced to  $\text{NH}_4^+$ , which is an undesirable side effect for the groundwater rehabilitation.

Thus, 1.345 mmol/L  $\text{CH}_3\text{OH}$  is the necessary amount for a total reduction of nitrate. Methanol has a density of  $0.7 \text{ g/cm}^3 = 700 \text{ g/dm}^3 = 700 \text{ g/L}$  and a molecular weight of 32 g/mol, therefore a 100% methanol-solution has  $700 \text{ g/L} : 32 \text{ g/mol} = 21.875 \text{ mol CH}_3\text{OH}$  per liter of methanol solution. Thus 1.345 mmol  $\text{CH}_3\text{OH}$  per liter of groundwater : 21875 mmol  $\text{CH}_3\text{OH}$  per liter of methanol solution =  $6.15 \cdot 10^{-5} \text{ L}$  methanol solution per liter groundwater are required, or related to  $1 \text{ m}^3$  groundwater 0.06 L of a 100% methanol solution.

#### 4.1.6.2 Fe(0) barriers

Like in the previous exercise (3.1.6.1) the question about the dimension of the reactive iron barrier and the corresponding uraninite precipitation must be solved iteratively. Elemental iron is added step by step via the keyword REACTION and the saturation index of uraninite is registered. If for instance 1, 2, 3, 4, and 5 mmol/L of Fe are added, the following saturation indices are obtained: -14.3401, -13.6202, -12.8359, -11.3031, +9.5288, i.e. uraninite gets supersaturated when adding between 4 and 5 mmol/L of Fe. Further refining the range, one can assess the supersaturation at 4.40 mmol/L. The results in Table 51 are obtained, promoting uraninite precipitation and registering the amount of dissolved uranium after the reduction of U(VI) to U(IV) by Fe and the subsequent precipitation as (probably amorphous)  $\text{UO}_2$ .

**Table 51** Decrease of the uranium concentration using  $\text{Fe}^0$  barriers of different iron concentrations

Fe [mmol/L] in reactive barrier	4.40	4.42	4.43	4.44	4.46	4.48
U [mol/L] in solution after reaction	8.7366 e-05	6.7663 e-05	5.7854 e-05	4.8089 e-05	2.8811 e-05	1.0582 e-05
U [mg/L] in solution after reaction	20.79	16.10	13.77	11.45	6.86	2.52

Since the requirement was to reduce uranium at least to one third of the initial quantity of 40 mg/L, the target concentration is 13 mg/L. Thus, at least 4.43 mmol/L = 247.4 mg/L of Fe have to be available. Assuming a flow-through of  $500 \text{ L/dm}^2$  these are  $247.4 \text{ mg/L} \cdot 500 \text{ L/dm}^2 = 123.7 \text{ g/dm}^2$ . Furthermore, if the barrier is to be in effective operation for about 15 years (5475 days) then  $123.7 \text{ g/dm}^2 \cdot 5475 \text{ d} = 677.3 \text{ kg of Fe per m}^2$  must be used. During operation 0.1115

mmol/L  $\text{UO}_2(\text{a})$  will precipitate, that is 30.1 mg/L, or 82.4 kg/m<sup>2</sup> for a flow-through of 500 L/d·m<sup>2</sup> in 15 years.

#### ***4.1.6.3 Increase in pH through a calcite barrier***

By setting up a reactive calcite barrier in the aquifer, the pH value of the initial acid mine water is increased from 2.3 to 6.25 at a calcite saturation of 50%. Hereby, 17.3 mmol/L or 1.73 g/L calcite dissolves, i.e. for a flow of 500 L/d·m<sup>2</sup> this amount is 1.73 g/L · 500 L/d·m<sup>2</sup> = 865 g/d·m<sup>2</sup>. The available 2500 kg/m<sup>2</sup> of calcite would thus be sufficient for 2500 kg/m<sup>2</sup> : 865 g/d·m<sup>2</sup> = 2890 days or 7.9 years, before the calcite barrier would be completely dissolved.

Yet after the reaction with calcite the water is strongly supersaturated with regard to gypsum, which consequently must be precipitated. After the precipitation of gypsum the pH is even slightly higher (6.356) than for pure reaction with calcite, 20.8 mmol/L, or 2.08 g/L of calcite dissolve. At a rate of 500 L/d·m<sup>2</sup> there would be 1040 g/d, i.e. it would take only 2402 days or 6.6 years until the barrier is completely consumed. Far more complicated is the precipitation of 17.5 mmol/L or 2.38 g/L of gypsum. For the assumed flow of 500 L/d·m<sup>2</sup> this quantity is 1190 g of gypsum precipitating each day, forming a coating on the calcite barrier, decreasing the permeability and thereby obstructing or even completely preventing any further calcite dissolution.

Alternatively dolomite (as a mixed mineral of Mg and Ca carbonate) or pure Mg carbonate (magnesite) could be used. Dolomite causes a pH increase to 6.439 dissolving 11.45 mmol/L or 2.11 g/L of dolomite. For a flow of 500 L/d·m<sup>2</sup> there are 1050 g/d, using up the supply of 2500 kg dolomite within 2500 kg : 1050 g/d = 2373 days or 6.5 years. As for the reaction with calcite, gypsum becomes supersaturated (SI gypsum = 0.26) and will precipitate. The resultant pH is 6.470 and dolomite dissolution is 12.15 mmol/L = 2.24 g/L (complete dissolution of the dolomite barrier after 2237 days or 6.1 year). Gypsum precipitation produces 9.475 mmol/L or 1.29 g/L gypsum, which is a reduction of 644.3 g/d (at a flow of 500 L/d·m<sup>2</sup>) compared to the pure calcite barrier, even though it is still too much for an effective long-term run of the reactive barrier.

For a pure magnesite barrier the pH increases to 6.533. Gypsum stays slightly undersaturated (SI = -0.08), thus is not precipitating and not forming problematic incrustations. An amount of 26.4 mmol/L or 2.22 g/L of magnesite is dissolved, resulting in an average life of 2252 days or 6.2 years. The higher cost for pure magnesite can be justified by the long-term effectiveness compared to a calcite or dolomite barrier.

## 4.2 Reaction kinetics

### 4.2.1 Pyrite weathering

*Question 1: What is the chemical composition of the seepage water discharging at the foot of the heap along the base sealing?*

The heap is covering an area of  $100 \cdot 100 = 10,000 \text{ m}^2$ . Hence, with a daily infiltration rate of 0.1 mm, 1000 liter of rainwater infiltrate every day. The volume of  $0.1 \text{ m}^3 \text{ O}_2$  equals 100 liter  $\text{O}_2$  that are entering the heap each day by diffusion. Because one mol of gas equals 22.4 L gas at atmospheric pressure, 100 liter equal  $(100/22.4) 4.463 \text{ mol}$  of  $\text{O}_2$ . The PHREEQC job for the solution of this task is done as follows: Distilled water (rainwater) is equilibrated with the  $\text{CO}_2$ - and  $\text{O}_2$ -partial pressures of the atmosphere, then the extra oxygen from the diffusion into the heap is added by using REACTION and at last the resulting water is put into equilibrium with pyrite.

In the process 1.347 mmol of pyrite dissolve per day and per liter, that equals 1.347 mol for 1000 liters. The pH value is 2.65 and the pE 2.79. Because the modeling started with distilled water, it contains only carbon (0.01704 mmol/L as  $\text{CO}_2$ ), iron (1.347 mmol/L as  $\text{Fe}^{\text{II}}$ ), and sulfur (2.695 mmol/L as S(6)) after the reaction. The element S(6) occurs in the following species (Fig. 78):

**Fig. 78** Species distribution for sulfur in the oxidation state +6 in the seepage water discharging at the foot of the heap along the base sealing

2. What happens when water at the foot of the heap is in contact with atmospheric oxygen?

To answer this question, the result of question 1 has to be saved in the PHREEQC input file with SAVE\_SOLUTION 3, recalled in a new job by USE\_SOLUTION 3, and subsequently equilibrium with the atmospheric partial pressure has to be adjusted.

The divalent iron is oxidized by atmospheric oxygen into trivalent iron, but only 13% of this iron occurs as free  $\text{Fe}^{3+}$  cation. The rest is bound in hydroxo and sulfur complexes (Fig. 79).

Fig. 79 Species distribution for iron in the oxidation state +3 in the seepage water discharging at the foot of the heap along the base sealing

After the reaction the following minerals are close to saturation or supersaturated (Table 52).

Table 52 Saturation index for some mineral phases after the discharge of the seepage water at the foot of the heap along the base sealing and after contact with atmospheric oxygen

Mineral	SI	Mineral	SI	Mineral	SI
$\text{Fe}(\text{OH})_3(\text{a})$	-0.41	JarositeH	-0.27	Goethite	5.48
Magnetite	-0.4	Maghemite	2.57	Hematite	11.93

Amorphous iron hydroxide, which precipitates rather spontaneously, is still undersaturated. Maghemite, goethite, and hematite do not usually precipitate spontaneously, but form as secondary mineral phases from hydroxides. That

means the trivalent iron mainly remains in solution through complexation reactions.

*3. How many years will it take until all pyrite in the heap is exhausted?*

To answer this question one does not even have to use PHREEQC. The heap has a volume of  $100,000 \text{ m}^3$  ( $100 \cdot 100 \cdot 10 \text{ m}$ ). 2% of it are  $2,000 \text{ m}^3$  of pyrite, which with a density of  $5.1 \text{ t/m}^3$  amounts to  $10,200 \text{ t}$  or  $10,200,000,000 \text{ g}$ / $119.8 \text{ g/mol} = 85,141,903 \text{ mol}$ . With a pyrite dissolution of  $1.347 \text{ mol/d}$  it takes  $85,141,903 \text{ mol}/1.347 \text{ mol/d} = 63,208,539 \text{ days}$  or  $173,2 \text{ years}$  until all pyrite is gone. During that time the water has a pH 2.65, and contains  $215 \text{ mg/L}$  of sulfate and  $75 \text{ mg/L}$  of iron (as Fe(II)). This result is only valid if there is no passivation of the pyrite surfaces and the mineral is not imbedded in a rock matrix that is weathering more slowly.

*4. How much carbonate has to be added during the heap construction to neutralise the pH value? Is it possible to reduce the amount of sulfate at the same time?*

The existing input file is extended by setting up equilibrium not only with pyrite but also with calcite.  $2.621 \text{ mmol}$  of calcite dissolve. The amount of pyrite dissolved is the same as in the absence of calcite ( $1.347 \text{ mmol}$ ). The pH value of 7.58 is in the neutral range. Thus, to neutralize the pH approximately 2 moles of calcite must be added for every mol of pyrite. The saturation index of gypsum is still clearly undersaturated ( $\text{SI} = -1.09$ ), i.e. that gypsum is not a limiting mineral phase and hence the sulfate contents stay more or less the same.

*5. How does the necessary amount of carbonate change when assuming that a  $\text{CO}_2$  partial pressure of 10 Vol% will develop within the heap as a result of the decomposition of organic matter?*

The increased  $\text{CO}_2$  partial pressure is implemented using the logarithm of its partial pressure in bar under the keyword EQUILIBRIUM\_PHASES. For a partial pressure of 10 vol%  $\text{CO}_2$  considerably more calcite must be available in the heap, since a significant amount of the  $\text{CO}_2$  is used for the dissolution of calcite. To reach equilibrium now  $6.288 \text{ mmol}$  of calcite are needed. For one mol of pyrite  $4.7 \text{ mol}$  of calcite must be added. The pH value is with 6.65 compared to 7.58 lower by almost one order of magnitude. Again no saturation is reached for gypsum.

#### **4.2.2 Quartz-feldspar-dissolution**

The input file for the solution of this task consists of the keywords SOLUTION, EQUILIBRIUM\_PHASES, KINETICS, RATES, and SELECTED\_OUTPUT. In the KINETICS block the total time in seconds and the number of steps must be

defined by the sub keyword -step. This step is done only once and it does not matter for which mineral. Numerical problems must be solved by choosing suitable parameters for -tol and -step divide.

**Fig. 80** Kinetics of the dissolution of quartz for four models with different temperatures and partial pressures

**Fig. 81** Kinetics of the dissolution of K-feldspar for four models with different temperatures and partial pressures

Fig. 80 and Fig. 81 show, that both quartz and K-feldspar show different dissolution kinetics depending on temperature and CO<sub>2</sub> partial pressure. The difference between quartz and K-feldspar is significant: while quartz reaches dissolution equilibrium after 150 to 550 days, K-feldspar does not show any equilibration even after 10 years for all of the four possible scenarios. To reach

saturation for K-feldspar in all four models, the simulation time would have to be about 1,000 years.

#### 4.2.3 Degradation of organic matter within the aquifer on reduction of redox-sensitive elements (Fe, As, U, Cu, Mn, S)

At the beginning of the degradation of organic matter the pE-value decreases significantly (Fig. 82). During this decrease the sulfate contents increase by the dissolution of pyrite. From a pE value of +2.7 onwards pyrite is supersaturated and precipitates, which causes a continuous decrease of the sulfate content. The zero-charged  $\text{CaSO}_4^0$  complex copies this behavior to some extent. The pH decreases slightly at the beginning and finally steadies at a value just over 6.

**Fig. 82** pH, pE, and sulfate concentration over a period of 10,000 days (approximately 27 years) by degradation of organic matter

Fig. 83 shows the undersaturation of some mineral phases of interest. If the saturation index is attained, the respective mineral is precipitated by the model and acts as a limiting phase (kinetics are not considered). The possible limitation by coffinite, uraninite, and pyrite from 500 days onwards (not distinguishable in the figure; coffinite is not a limiting mineral phase any more from 2000 days on; furthermore it is questionable that coffinite forms under these conditions) is remarkable. Kaolinite is supersaturated after 2,000, calcite after 7,000, and  $\text{Al}(\text{OH})_3$  after 10,000 days. Jurbanite is supersaturated from the beginning on. An important statement is that, at least under the defined boundary conditions, pyrite can form simultaneously with uranium minerals from a pE value of approximately 2.7 and lower. Before that, the occurrence of pyrite has no significant influence on the concentration of uranium. Moreover, it is important to note that organic matter

is available over the whole period of time, in contrast to calcite, which is already consumed during the first reaction step. The continuous increase of inorganic carbon results from the formation of  $\text{CO}_2$  by the degradation of organic matter. Regarding  $\text{CO}_2$  the model assumes a closed system:  $\text{CO}_2$  degassing is excluded. The overall influence of calcite is rather small. It causes the pH increase at the beginning of the modeling from 2.3 to 3.39 and has influence on the time of calcite precipitation. Since at the beginning only a small amount of calcite is dissolved, the saturation index of gypsum stays in equilibrium and no precipitation of gypsum was considered.

**Fig. 83** Selected saturation indices compared to pE and pH values during the degradation of organic matter over a period of 10,000 days

Manganese does not change during the whole time of modeling and occurs as  $\text{Mn}^{2+}$ . Copper behaves in a different way; it is in the end responsible for the sudden changes in the pE value. The occurrence of Cu(1) together with As(3) (Fig. 84) and the re-transformation into Cu(2) at pE-values below -1.87 is also interesting.

For a closer look on the reactions at the beginning of the degradation, the modeling was redone with unchanged boundary conditions in 100 time steps for a period of 600 days. Fig. 85 shows better than Fig. 82 and Fig. 83 the stepwise decrease of the pE value. The first drop is related to the occurrence of Fe(2), the second to the elimination of Fe(3) and the reduction of As(5) to As(3). Shortly after that the reduction of U(6) to U(4) occurs. In the model uraninite and coffinite precipitate spontaneously and hence the uranium concentrations are significantly reduced.

Fig. 84 Changes in the speciation of  $\text{Cu}^+$  and  $\text{Cu}^{2+}$  in relation to pE and pH values during the degradation of organic matter over a period of 10,000 days

Fig. 85 Changes in the speciation of iron, arsenic, and uranium compared to pE and pH values during the degradation of organic matter over a period of 600 days

4.2.4 Degradation of tritium in the unsaturated zone

Instead of the fictitious initial solution given in the example of an impulse-like input function of a tritium concentration of 2,000 T.U., a solution of the averaged

concentration over a period of 5 years is used (climate station: 06/1962 - 06/1967 1022 TU). The “punch frequency” under the keyword TRANSPORT must be changed from 10 to 5, since every fifth time step (5 years) shall be printed in the output. The six further solutions from 1967-1997 with decreasing tritium concentrations are used as SOLUTION 0 instead of the modeling “30 years no tritium”. The jobs are added one after another, separated by END. The definition of the transport parameters (number and length of the cells, time steps etc.) must only be done once, when the keyword TRANSPORT is used for the first time (for the modeling of the first 5 years). For the modeling of the further 6 times 5 years only the keyword TRANSPORT is sufficient, all parameters defined in there are taken over from the first definition.

Fig. 86 shows the modeled tritium concentrations in the unsaturated zone after 5, 10, 15, 20, 25, 30, and 35 years. Contrary to the modeling with an impulse-like tritium input (Fig. 59) the concentrations in the uppermost meters of the soil do not immediately drop back to zero because some tritium-containing water continues to infiltrate, even though with lower tritium concentrations. Thus, the tritium peaks do not show a symmetrical curve as with the impulse-like input, but a slightly left-sided distribution.

**Fig. 86** Vertical cross section of tritium in the unsaturated zone (0-20 m depth) for the climate station Hof-Hohensaas, Germany after 5, 10, 15, 20, 25, 30, and 35 years

### 4.3 Reactive transport

#### 4.3.1 Lysimeter

Fig. 87 shows the concentration distribution of Ca, Mg, K, Cl, Fe, and Cd in the lysimeter column. Chloride behaves like an ideal tracer and flows through the lysimeter column only influenced by dispersion. Iron apparently does the same, but this is an artifact because no selectivity constant is defined for the predominating species  $\text{Fe}^{3+}$ . There is one selectivity constant defined for  $\text{Fe}^{2+}$ , but this species only occurs in negligible amounts ( $1.459\text{e-}07$  mol/L). Calcium and magnesium are preferably exchanged for cadmium. This leads to the peaks, occurring after one complete column exchange, that are the sum of the concentrations in the initial water and the acid mine water. As soon as calcium and magnesium are completely exchanged for cadmium, the concentrations decrease to the level of the acid mine water, which is further added to the column. Cadmium only appears at the column's outlet, when all exchanger sites are occupied, i.e. when the entire volume of the column is exchanged 1.5 times. Thereby,  $\text{Cd}^{2+}$  ions occupy both the exchanger sites of  $\text{Mg}^{2+}$  and of  $\text{Ca}^{2+}$ . That is why cadmium already appears after 1.5 and not only after 2 exchanged column volumes. Potassium is only exchanged to a small extent, sorption and desorption balance one another.

Fig. 87 Concentration distribution of Ca, Mg, K, Cl, Fe, and Cd in the lysimeter column

#### 4.3.2 Karst spring discharge

Using the keyword TRANSPORT, PHREEQC always expects an initial solution in the cells, defined as SOLUTION 1-n (here: 1-40). For this exercise it is possible

to simply use the analysis of the water flowing in the karst channel. The same analysis is used as SOLUTION 0 (input solution). The only difference is that for the kinetic transport modeling the partial pressures for  $\text{CO}_2$  and  $\text{O}_2$  are adjusted to atmospheric conditions by means of EQUILIBRIUM\_PHASES 1-40. It is important that also within the keywords KINETICS, RATES, and TRANSPORT all 40 cells are considered. A number of 50 shifts is sufficient for the complete exchange of the water, after which a steady state is attained. The results of PHREEQC always refer to one liter of water. Thus, the respective conversions must be done; from the stated value in mol calcite/L  $\cdot 0.5 \text{ L/s}$  (discharge)  $\cdot 86400 \cdot 365 \text{ s/a}$  to mol calcite/a, and then from mol calcite/a  $\cdot 100 \text{ g/mol}$  to g calcite/a.

The result of the modeling is depicted in Fig. 88 as the precipitated amount of calcite per year in kg/a for the modeled 400 m in the karst channel after the discharge. The calcite supersaturation decreases within 400 m respectively 27 minutes from 1.58 to 0.16. Despite of the small discharge of 0.5 L/s, the amount of precipitation is 3354.85 kg of calcite per year within the first 400 m with an associated release of 1727.5 kg of  $\text{CO}_2$  into the atmosphere.

**Fig. 88** Calcite saturation index and amount of calcite precipitated per year for a discharge of 0.5 L/s in a 400 m long karst channel with a flow velocity of 0.25 m/s assuming turbulent mixing ( $P(\text{CO}_2) = 0.03 \text{ Vol\%}$ ).

The amount of  $\text{CO}_2$  can be calculated from the difference of the concentrations of inorganic carbon dioxide at the beginning (6.64 mmol/L) and at the end of the channel (2.02 mmol/L). This amount is 4.62 mmol/L or 873.72 kg C/a. Furthermore, it is known that 3354.85 kg of calcite precipitate per year, which amounts to 402.58 kg of carbon per year ( $3354.85 \text{ kg/a} / 100 \text{ mol/L}$  (molecular weight of  $\text{CaCO}_3$ )  $\cdot 12 \text{ mol/L}$  (molecular weight of carbon)). The difference between the initial carbon concentration and the concentration, that is lacking at

the end of the channel but was not precipitated, must be the quantity released:  $873.72 \text{ kg C/a} - 402.58 \text{ kg C/a} = 471.14 \text{ kg C/a}$  or  $1727.5 \text{ kg of CO}_2/\text{a}$ . Alternatively, it is possible to calculate the difference between the amount of  $\text{CO}_2$  at the beginning and at the end of the karst channel ( $2.55 \text{ mmol/L} - 0.45 \text{ mmol/L} = 2.10 \text{ mmol/L}$ ), then reduce the difference of the contents of inorganic carbon at the beginning and at the end by that value ( $4.62 \text{ mmol/L} - 2.10 \text{ mmol/L} = 2.52 \text{ mmol/L}$ ) and finally convert the result, as explained above, into  $\text{kg of CO}_2/\text{a}$  ( $1748.4 \text{ kg CO}_2/\text{a}$ ). The deviations resulting from the two different ways of calculation ( $1727.5 \text{ kg CO}_2/\text{a}$  versus  $1748.4 \text{ kg CO}_2/\text{a}$ ) are within the limits of rounding errors.

#### 4.3.3 Karstification (corrosion along a karst fracture)

To model the karst fracture the keyword TRANSPORT is used and 30 elements are defined by the sub keyword -cells. For the fracture being 300 m long the length of the cells is 10 m each. The number of 30 shifts is required to exchange the water volume one time completely. According to the assumed flow velocity the variable -time step is set to 360 seconds (= 0.1 hours). Using -punch 1-30 all 30 cells are printed in the output, with -punch frequency 30 only the result after 30 shifts is considered for all of those 30 cells. The adjustment of the equilibrium during transport can be done using EQUILIBRIUM\_PHASES. It is important to add 1-30 behind the keywords SOLUTION, EQUILIBRIUM\_PHASES, and KINETICS in order to consider all 30 cells.

By using the keyword USER\_GRAPH, data are directly written to the spreadsheet GRID within PHREEQC and the graph is created automatically in the folder CHART. The script is as follows:

```
USER_GRAPH
-headings x Ca C SI(calcite)
-chart_title Karstification
-axis_titles "distance [m]" "concentration [mol] and SI-calcite"
-axis_scale y_axis 0 0.005
-axis_scale secondary_y_axis -3 0.0 1.0
-initial_solutions false
-plot_concentration_vs x
10 GRAPH_X DIST
20 GRAPH_Y tot("Ca"), tot("C")
30 GRAPH_SY SI("Calcite")
```

To display the secondary Y-axis for the calcite saturation index besides the primary Y-axis with the concentrations for Ca and C, “Chart options”/“Show secondary y-axis” must be chosen by click on the right mouse button in the graph. The result of the modeling can be seen in Fig. 89. The figure depicts a convergence to the calcite equilibrium. However, the saturation index shows that

even in the last cell the equilibrium is not reached yet, and thus, carbonate is still dissolved in small quantities (corrosion).

**Fig. 89** Corrosion in a fracture showing convergence to the calcite equilibrium with increasing distance

#### 4.3.4 The pH increase of an acid mine water

The acid mine water is defined as SOLUTION 0 and the water in the carbonate channel as SOLUTION 1. Within the keyword KINETICS 1-10 the calculation tolerance as well as the initial and the total mole mass of calcite can be defined. Obligatory are only the parameters 50 and 0.6. These are needed by the BASIC program, which must be implemented within the keyword RATES. Here, we use the BASIC program listed at the end of the database PHREEQC.dat. If the database PHREEQC.dat is used (which is not free of troubles, since there are, e.g., no data for uranium) or if the paragraph is copied into another database, it is not necessary to define a RATES block in the input file. PHREEQC uses automatically the RATES block from the database. Yet, if any other kinetic rates are to be used, the BASIC program must be copied into the input file under RATES. In any case, the KINETICS block is required.

Using the keyword TRANSPORT the model is built from 10 cells and 15 shifts. Flow velocity is defined to 1 m/s by setting -length and -time\_step to 50. By that, the total length of the channel is 500 m and the total exposure time 500 s. To get the required information in a selected output file, the input definition must look as follows:

```
SELECTED_OUTPUT
-file amd_kin.csv
```

-totals Ca C Fe  
-molalities SO4-2 CaSO4  
-saturation\_indices gypsum calcite  
-kinetic\_reactants calcite # how much calcite is dissolved by KINETICS?  
-equilibrium\_phases gypsum Fe(OH)3(a) # how much gypsum and  
# Fe(OH)3 is dissolved by  
# EQUILIBRIUM?

Fig. 90 shows that the largest changes in pH value take place in the middle of the carbonate channel. There, also the decrease of iron concentrations due to iron hydroxide precipitation takes place. Slightly more moderate are the increase of Ca by calcite dissolution and the decrease of sulfate by gypsum precipitation. The significant decrease of inorganic carbon in the acid mine drainage at the beginning of the channel is caused by degassing of CO<sub>2</sub> to the atmosphere.

**Fig. 90** Concentration changes in an acid mine water while flowing through a 500 m long carbonate channel

Fig. 91 shows the saturation index for calcite, which increases from almost -12 to about -2.27 in acid mine water, but does not reach saturation. Furthermore, the figure depicts the amounts of dissolved calcite in mol as well as the amounts of precipitated gypsum and iron hydroxide over the simulation time. It can be seen that a channel of 300 m would have a very similar treatment effect as the one modeled of 500 m length. Yet, modeling of gypsum and iron hydroxide precipitation was done without considering kinetics, but assuming a spontaneous precipitation. The modeling with a partial pressure of 1 vol% CO<sub>2</sub> shows the same behavior at lower pH values (approx. 0.5 pH units) and higher carbon contents.

**Fig. 91** Dissolution of calcite, precipitation of gypsum and iron hydroxides, and the development of the calcite saturation index for the AMD water shown in Fig. 90

#### 4.3.5 In-situ leaching

The fracture system is modeled as a 1D aquifer with high permeability (20 mobile cells with the numbers 1-20), each one connected to immobile cells (number 22-41, number 21 is reserved for the column's discharge). The content of the immobile cells can only be transferred to the mobile cells by diffusion. The value for  $\alpha$  is calculated from Eq. 102 assuming  $D_e = 2 \cdot 10^{-10} \text{ m}^2/\text{s}$  (range from  $3 \cdot 10^{-10}$  to  $2 \cdot 10^{-9}$  for ions in water, approximately one order of magnitude less for water in clays),  $\theta_{im} = 0.15$ ,  $a = 0.1 \text{ m}$  (thickness of the stagnant zone accompanying the fracture), and  $f_{s \rightarrow 1} = 0.533$  (Table 16)

$$\alpha = \frac{D_e \theta_{im}}{(a f_{s \rightarrow 1})^2} = \frac{2 \cdot 10^{-10} \cdot 0.15}{(0.1 \cdot 0.533)^2} = 1.056 \cdot 10^{-8}$$

The fracture volume  $\theta_m$  was set to 0.05, the pore volume  $\theta_{im}$  to 0.15.

Already after 30 days the concentrations for the depicted elements U, S, Fe, and Al drop. Further in the simulation the decrease is much smaller (Fig. 92). At the end of the data record, at a fictitious time of 230 days, the concentration of the groundwater is shown as a target value. However, to get down to this concentration, the simulation would have to be continued for many more years because of the slow diffusive transfer of contaminants from the immobile to the mobile cells.

Summing up the uranium concentrations for the time steps 1 to 20 gives the amount of uranium in the fractures (3.2 mmol). Because the pore volume is 3

times more than the fracture volume (0.15 compared to 0.05), the uranium concentration in the matrix is also 3 times higher (9.6 mmol). The sum from time steps 21 to 201 is the amount of uranium discharged from the matrix over a period of 180 days (0.298 mmol). This simple calculation shows that after 180 days only about 3.1 % of the total uranium left the matrix via diffusion. Because the process is almost linear, the total time for uranium removal can be estimated to about 16 years.

**Fig. 92** Simulated concentration at the pumping well over a period of 200 days (fracture volume 0.05, pore volume 0.15, 10 cm of pore matrix connected to the fracture), points on the right side mark the target concentrations.

Changing the parameters as required by the exercise, the following value for the exchange parameter results:

$$\alpha = \frac{D_e \theta_{im}}{(af_{s \rightarrow 1})^2} = \frac{2 \cdot 10^{-10} \cdot 0.05}{(0.01 \cdot 0.533)^2} = 3.52 \cdot 10^{-7}$$

If this value is used for modeling together with the smaller value for the size of the connected matrix with 0.01 m, the discharge behavior looks completely different (Fig. 93) For instance the uranium concentration has dropped to the groundwater values already after 100 days, all uranium is removed.

Fig. 93 Simulated concentration at the pumping well over a period of 200 days (fracture volume 0.05, pore volume 0.05, 1 cm of pore matrix connected to the fracture)

#### 4.3.6 3D Transport – Uranium and arsenic contamination plume

The first task is very simple: just open in the WPHAST GUI the *INITIAL\_CONDITONS* and *CHEMISTRY\_IC*, then double-click *Default* and delete the 1 under *surface*. You may as well remove the surface statement from the file \*.chem.dat, but even without removing this statement in the PHREEQC-Files the model does not take into account any surface complexation after the one single change in the phast-input file. Input files and the results can be seen on the enclosed CD in the folder 3\_Reactive-transport/6a\_3D-transport.

The solution of the second task is as follows: In addition to generating a new property (zone 5 with EQUILIBRIUM\_PHASES 2) within WPAST the relating change has to be made in the \*.chem.dat file:

USE Solution 1

Phases; Iron; Fe +2.0000 H+ +0.5000 O2 = + 1.0000 Fe+2 + 1.0000 H2O  
log\_k 59.0325; -delta\_H -372.029 kJ/mol

EQUILIBRIUM\_PHASES 2; Iron ; Uraninite(c) 0 0; Calcite 0 0; pyrite 0 0  
END

The input files and the results can be seen in the folder 3\_Reactive-transport/6b\_3D-transport.

To solve the third task, just add the following block in the PHREEQC control file within the first section (before the first END statement):

# SURFACE\_SPECIES

#  $\text{UO}_2(\text{CO}_3)_2$

log\_k 12.0

log\_k 5.0

No changes have to be made to the WPHAST-input file. Rerun the PHAST model and you will see that much more uranium is sorbed than in the introductory example (log\_k for  $\text{UO}_2(\text{CO}_3)_2$  are preliminary data only) and the arsenic sorption is less due to competitive surface reactions. The input files and the results can be seen in the folder 3\_Reactive-transport/6c\_3D-transport.
